THE CURE OF EARLY PARESIS*

CHARLES L. DANA, M.D., LL.D.
NEW YORK

In a paper read before this society five years ago,[1] I made a contention that it was possible to arrest, and probably to arrest permanently, certain cases of paresis when they were observed in the earliest stages and submitted to prompt and prolonged treatment. To the objection that the cases cited in illustration of my point, were not really cases of paresis, but of cerebral syphilis or "pseudoparesis," I could answer only by contending that there were no possible criteria by which we could distinguish "pseudoparesis" and certain forms of cerebral syphilis from paresis itself, except by saying that when the patients recovered, the cases were false, and when the patients died the cases were real. In the pseudoparetic cases as in true cases, we have headaches, convulsions, syncopal and aphasic attacks, disturbance of the pupillary reflexes, tremors, cranial nerve palsies, even attacks of hemiplegia, lymphocytosis of the cerebrospinal fluid, and positive reaction to Wassermann's test. In each kind of case also, we find changes in character, increased irritability, inability to conduct business affairs, defects of attention, somnolence, confusion and quick exhaustibility of the mental processes on exertion. In cases in which paresis is firmly established, with grandiose delusions, real dementia, marked facial and tongue tremors, speech defects, involvement of the pyramidal tracts. I make no claim that the disease can receive, at the most, more than a remission.

The clinical facts on which my contention is based, have been so abundant and positive since I first wrote on this subject that it seemed almost unnecessary to emphasize the point further. I am led to do so, however, because my view has been misunderstood by some who have jumped to the conclusion that I have asserted that paresis can be cured when fully developed; also, because my view as to the essential unity of nervous syphilis and parasyphilis has been so strongly confirmed by the discovery of the pale spirochete and the evidence of its activity by Wassermann and other tests in parasyphilitic conditions.

The observations of Drs. Noguchi and Moore[2] show that in general paresis and in cerebral and nervous syphilis, there is a positive reaction both to the butyric acid and the Wassermann test; also that there is a practically equal evidence of lymphocytosis in the cerebrospinal fluids. Similar results were obtained by Dr. Rossanoff[3] in his observations recently presented before the New York Academy of Medicine. Dr. Kaplan's observations presented at the same time lead to the same conclusions. It is very well established, then, that so far as the blood and the cerebrospinal fluid tests go, there is no qualitative difference in the reactions between paresis and so-called syphilis of the nervous system. There is indeed a rather stronger and more positive reaction in paresis than in the ordinary syphilis of the nervous system.[4]

The attempt to find a test which should distinguish between paresis and nervous syphilis or "syphilitic neurasthenia," has been made by Nonne and some of his followers. The most recent observations regarding the utility of what is known as the Phase I Test of Nonne failed to show that it is of any distinct value in distinguishing between these two conditions (Noguchi and Moore[2]). It follows, then, that since there is an essential underlying unity between true paresis, and "luetic neurasthenia," "pseudoparesis," "nervous syphilis," there is no reason to suppose that if we can cure one, we can not also forestall and even cure the other. This is what I assert to be possible and also, that it is not infrequently done. Over and over again, it has been my experience to see luetic patients suffering in almost the same way, nervously and mentally, and yet, in one case, after a time, a true paresis develops, and in the other case it does not. And, furthermore, it has been my experience to see patients who have, clinically, developed nearly all the signs of paresis, improved, and remained practically well for years.[5]

---

* Read before the New York Psychiatrical Society, Nov. 3, 1909.

[2] Noguchi, H., and Moore, J. W.: The Butyric Acid Test for Syphilis in the Diagnosis of Metasyphilitic and Other Nervous Disorders, Jour. Exper. Med., July 17, 1909, abstr. in THE JOURNAL A. M. A., Aug 14, 1909, liii, 591.

[3] One of Dr. Rossanoff's conclusions is the following: "Inasmuch as the Wassermann reaction and the butyric acid reactions seem to indicate syphilis only when it exists in an active or potentially active form, their regular occurrence in general paresis would tend to prove that that disease is a manifestation of active syphilis, of activity of the *Spirochæta pallida*. While the evidence for this view is not as yet complete, it is sufficient to justify its being used as a basis of therapeutic essay." Rossanoff also cites a case which was diagnosticated general paresis. The patient, however, recovered under treatment by mercuric injections, whereupon the diagnosis was changed to cerebral syphilis. While it cannot be proved, clinical experience in other cases justifies one in saying that if this patient had not received treatment he would have died with the symptoms of paresis. Cases like this have occurred in my experience and have been potent in forcing me to my conclusions as to the nature and management of this disease.

[4] Apelt's later observations (Arch. f. Psychiat., xlvi, No. 1) only show that the "Phase I" or globulin reaction does not occur so often in so-called cerebral lues or luetic neurasthenia as it does in tabes and paresis, but it does occur, and all the serum and blood tests indicate only a quantitative, not a qualitative, difference between the conditions.

[5] Sometimes cases which present mainly the appearance of cerebral syphilis do not improve under treatment, but go on steadily to a fatal termination with all the symptoms of paresis. Two patients came under my care at about the same time, beginning in the same way. One is now apparently in active health; the other died of paretic dementia. There must, then, be some plus factor in the matter which is potent to bring about the unfavorable result. This may be inadequate or belated treatment, or it may be a more degenerate, unstable brain. The luetic poison quickly brings about hopeless toxic changes in abiotrophic cells. Paresis that is fatal, then, is that in which the luetic infection is severe and uncontrollable, or that in which the brain-cell, being congenitally weak, easily falls prey to the toxin. This is the only difference which I can see between cerebral syphilis and "parasyphilis."

The ordinary, and perhaps I should say asylum view of prognosis of paresis has been recently presented by Dr. Green,[6] who made a very careful study of 200 cases, with reference to this point. He puts the limit of the duration of the disease at five years, this occurring only in the young; and he does not speak even of the possibility of cures, or long remissions. Such a view expresses, I think, a narrow and misleading conception of the malady, for paresis exists sometimes for years before it reaches the alienist or the hospital. A writer in one of the medical weeklies, during the past summer, also states unequivocally that paresis is not only never cured, but surely and always kills, i. e., it is not even permanently arrested. This also expresses what I should term a very juvenile view of paresis. Quite appropriately this writer quotes a French novelist in support of his position, but does not, I think, get any apperception of some more serious writers. As against Guy de Maupassant, I would quote Alzheimer, who states that he has most positive evidence that paresis has remained unprogressive for many years.

I wish now to put on record the final history of the cases which I reported five years ago, as an illustration of arrest in preparetic states. The details of the early history of the cases are given in the article referred to.[1] I shall add a few further reports of cases illustrating the clinical fact which I am trying to prove, for I know that it is only by the presentation of such data, accurately and impartially given, that any conviction can be produced; the minds of many alienists, at least, seem to be absolutely fixed in an attitude of pessimism towards the prognosis of paresis in any of its stages. The cases are referred to in the order they were reported originally.

Case 1.—A broker, aged 40, had an attack of melancholia, with the somatic symptoms indicating paresis; that diagnosis was made in his case. He had tremors and Argyll-Robertson pupils, but he had shown no dementia. He improved in the sanitarium and kept well for three years afterward, at which time I reported the case. He continued well for four years more, but he lived a life of great self-indulgence. He had losses in business and finally developed genuine symptoms of paresis and died in about a year. He had had, therefore, a remission of seven years, during which he was in every respect a normal man.

Case 2.—The patient had continued well for four years from the time when I saw him, when his symptoms were marked. He had had a luetic infection twelve years before. His symptoms were those of convulsions, speech disturbance, feeble memory and depression. He has continued well, and is now in active business. It is eight years since he recovered.

Case 3.—A man, aged 34, had a speech disturbance, Argyll-Robertson pupils, facial tremor and depression to the point of melancholia. When I reported his case he had been attending to his work and was well for the last three years. I saw him again in the past year and he had continued well, so that his remission has thus far lasted eight years.

Case 4.—A lawyer, aged 30, had all the evidences of a beginning tabo-paresis. The progress of his disease was arrested, and for seven years he has been able to do his professional work with a fair degree of success.

Case 5.—A broker, aged 40, had had an infection, his trouble began with a violent epileptic attack, followed by periods of maniacal excitement. For a year he had a great deal of mental irritability and depression, and a certain degree of weakness of comprehension and judgment. He has now continued well for six years since the first attack.

Case 6.—A man, aged 43, a broker, lost all his money in Wall Street, and then tried to steal some to make good. He developed a melancholia and killed himself.

Case 7.—This was one of those types of luetic infection, followed by anxious depression or a mild form of hypochondriacal melancholia. For twelve years the patient used to have an injection of mercury, every two weeks. It is now nine years since he was under systematic treatment and he continues well.

The following further cases illustrate the preparetic state and its possible outcome:

Case 8.—T. S., aged 46, lawyer, came to me in October, 1906. There was no hereditary history of importance. His father lived to 70, his mother died at 60, of an accident. The patient was married and had three healthy children. He had contracted lues about twenty-three years before coming under my observation. He suffered severely and though he was treated, his health broke down and he had to rest from business. After his recovery, i. e., for about twenty years, he had been quite well and had seen nothing of doctors until his present illness. About three and one-half years before I first saw him he suffered from sexual weakness, which had gradually progressed till he had become practically impotent. Of late his bladder had been a little weak. Two years before coming under my care he had lost consciousness suddenly and was aphasic for two days. His capacity to speak in court had been lessened since then. One year before the time when I saw him he had an attack of severe vertigo. Since then his mental powers had been lessened. He could not work long, could not concentrate, was forgetful, and had attacks of vertigo. He was very somnolent, sleeping ten hours at night and in the afternoon. He was depressed, emotional and unable to do much work of any kind. His gait and stature were normal, speech clear, handwriting much impaired. The knee-jerks and ankle-jerks were present but uneven. The pupils were uneven and did not react to light, but did to accommodation. The left pupil was irregular in shape. The patient had no anesthesias, lightning pains or ataxia. There was tremor of the hands and the face showed distinct facial tremor. The main mental symptoms were incapacity to work, mental inadequacy, defective memory, emotional excitability (irritability and depression) and somnolence. The physical symptoms were changes in deep reflexes, Argyll-Robertson pupils, facial tremor, defects of handwriting, sexual impotence without local cause, as attested by Dr. Eugene Fuller, who saw him in consultation, and vesical weakness. It was six months before the patient improved very much but at the end of that time he was very much better, except of the sexual impotence, and the pupils. His memory was good, his somnolence and apathy better. A letter received from him recently states that he is well, nearly three and one-half years since I first saw him.

Such a case as this is illustrative of a type which I have also seen progress till all the marks of paresis are developed.

Case 9.—J. E., aged 43, single, occupation engineer. The history furnished by his family physician, Dr. Parslow, is as follows: The patient's father died of Bright's disease, at 69; the mother was living in good health; he had four sisters all living. One had epilepsy for some years, but recovered. Three aunts died of tuberculosis.

The patient was always robust; used alcohol and tobacco moderately. His habits were excellent, with the exception of sexual excess, which undoubtedly made serious inroads on the patient's vitality. About three weeks after connection, in the latter part of 1901, three hard chancres appeared on the dorsum of the penis, followed by adenitis, roseola, etc. The secondary stage ran a mild course. Mercurial treatment was faithfully carried out. About one year after the primary sore, the patient was stricken with left hemiplegia. At this time, a neurologist saw him. Mercury by inunction was pushed. The motion of the left arm was seriously impaired, but improved. After the patient was up and around, it was noticed that he would fall asleep at his work, especially after eating; he was very hard to arouse mornings, even after ten or twelve hours' sleep. As he was in charge of complicated machinery, his employers had to displace him. His friends noticed that he acted queerly at times. Dr. Parslow never noticed any delusions or hallucinations. The patient wept easily, and his mental depression was marked; his countenance changed from a bright and intelligent to a dull and stupid expression. He was given iodids in large doses, but failed to improve.

---

[6] Green: Jour. Ment. Sc., 1908 or 1909.

When examined by me, he still showed some evidences of the left hemiplegia, the arm being somewhat contractured, and there were slight athetoid movements in the left hand. There was no anesthesia or ataxia. The reflexes were exaggerated, more on the left than on the right, but there was no clonus. The pupils were sluggish, but not actually of the Argyll-Robertson type. Mentally, he was simply very slow and forgetful: did not have even the ordinary school knowledge, nor could he recall the ordinary events of the day. He would fall asleep during the daytime and sleep all through the night. He had no cranial nerve palsies; no speech defects, but had a little tremor of the face and hands. He did not show any actual neglect of the person, and his sphincters were intact. He could read a little and write imperfectly. His condition had been gradually getting worse, notwithstanding large doses of the iodid of potassium, amounting to 120 grams a day.

The patient was put on hypodermic injections of salicylate of mercury, and gradually began to improve, and in about six months' time he seemed well, and went back to his work.

I saw him a year ago, five years after my first visit. He was then well mentally in every way. His speech was good, his memory clear, and he simply had some relics of his old hemiplegia.

This is a case of cerebral syphilis, but it was passing into dementia. The patient already had tremor, sluggish pupils, exaggerated reflexes. He was dull, slow, had lost his knowledge of things, was extremely forgetful, queer in actions, depressed, emotional, somnolent and partially demented.

Case 10.—E. A. M., male, aged 52, married, with two healthy children, came to see me first in May, 1906, suffering from tabetic pains. He had had a luetic infection at the age of 20, and was thoroughly treated for two years; he had had no luetic manifestations since then. He had been a hard worker at the dry-goods business. His habits were good; he used no alcohol or tobacco in excess. In 1898 he broke down with what was called "nervous prostration," and was unable to work for about six months. Two years later, in 1900, he began to have the characteristic pains of tabes, and had been treated for these symptoms and these alone, since that time.

Status in 1906: The gait was normal; there was slight Brauch-Romberg sign present, slight ataxia of the hands to the finger-nose test. Argyll-Robertson pupils, unequal in size, knee-jerks and ankle-jerks absent, tremor of the facial muscles and of the hands, no hypotonia, no anesthesia, bladder slow, sexual function very weak, tachycardia, but no valvular lesion. Mentally, the patient was irritable and quite forgetful; he had a slightly exaggerated manner, was a little *exalté*, was easily confused, could not play cards without making mistakes, could not sign his name on account of nervousness and tremor. He was somnolent during the day, falling asleep at his desk, was not able to read except for a few moments, was unable to do his work well, becoming easily confused and exhausted. There was a general change in his character, so marked that his wife came to consult me about it. He had no delusions, but was somewhat depressed.

The diagnosis, in 1906, was tabes and developing tabo-paresis. November, 1909, after several months' rest and treatment part of the time at a sanitarium, the patient returned to business and he has continued at it ever since. I have seen him at intervals during the past three and a half years. He is now mentally normal; he is no longer forgetful and can attend to his work. He can write and dictate readily. Facial tremor is gone. The tabetic symptoms are the same, almost exactly, as they were three years ago.

Case 11.—W. D., aged 30, married, denies infection. In 1902 he gradually developed a spastic paraplegia with bladder and sexual weakness, the disease taking the course of Erb's syphilitic spinal paralysis. In the fall the patient developed delusions of grandeur, and when examined by me he had all the somatic and mental symptoms of general paresis, with facial tremors, Argyll-Robertson pupils, and involvement of the pyramidal tracts. This diagnosis was confirmed by Dr. Frederick Peterson and the physician in charge of the institution to which the patient was committed. He was insane and delusional for nearly a year, but gradually improved, and has now been practically well of his mental trouble for over seven years. He has not known quite the mental vigor of his former years, and his spinal symptoms have remained about the same. The total duration of the condition is now nearly eight years.

This is a remission in general paresis, and it is not one of the class of cases on which I base my remarks. It is admitted by all that there may be long remissions in general paresis.

I could cite other cases from my notes, but I prefer to get the evidence of other neurologists, and Dr. Joseph Collins has kindly placed the two following cases at my disposal:

Case 12.—A man, aged 45, stock-broker, unmarried, was seen May 31, 1904. He had had syphilis when 23, an apparently moderate infection, treated by a prominent specialist for three years and pronounced cured. When 31 years old the patient had an attack of diphtheria; when 38, an attack of typhoid fever.

The first symptom of the present disorder, of which the patient is cognizant, occurred in 1903. He was in bathing. The propinquity of a certain person was responsible for extreme erethism, followed after a long time by orgasm. The patient experienced a profoundly disagreeable sensation in the head, and had a feeling of confusion and syncope. Following this he was in bed for a fortnight, and his physician who treated him, said that he had a heat-stroke. After that time the patient was subject to periods of profound depression. He lacked initiative, was moody, sullen, unsociable, and impotent. He frequently made mistakes in his orders and thought he had to give up business. Depression was his worst symptom. The pupils were unequal; one knee-jerk was absent, and there was distinct slowing of speech. This man took an enormous amount of mercury, by hypodermic injections and inunctions, and is to-day practically well. The physical signs remain the same, save that the speech has become distinct. He is able to transact his business as well as ever.

Case 13.—A man, aged 46, had syphilis when 21; he was rather alcoholic. When 38 years old he developed symptoms of mental confusion, associated at times with violence, but depression was his chief symptom. Gradually he became indifferent to his family, exhibited loss of self-control and was most easily excited and annoyed. Examination showed pupils that were unresponsive to light, slight tremor of the lips, tongue, and hands, and exaggerated knee-jerks. He seemed to have insight into his condition and explained his inability to work by saying that he was weak. He would frequently make mistakes in writing, however, and displayed evidences of marked forgetfulness. He was put under intensive mercurial treatment, and to-day, six years after I first saw him, he is running a store.

The question in all these cases, of course, comes up whether these patients really were suffering from paresis in an extremely early stage. Some authorities seem to take the position that we can never be sure we have a a case of paresis until the patient is dead, and the characteristic anatomic changes are found in the cortex of the brain. This anatomic test of the existence of paresis, is an unworkable one, and would make the talents and acuteness of the clinician practically of no value. Besides, it seems to me to be utterly without foundation. I do not believe that in the very early stages of paresis any anatomic change exists which could be detected by the microscope, and if we have to wait for our diagnosis of the disease until these anatomic changes occur, I can well agree that the prognosis must always be hopeless. But it is my conviction that we can recognize the malady before any appreciable changes do occur or, at least, changes which are beyond hope of repair or arrest. Let me illustrate this position by the following history:

Case 14.—A young man, a lawyer, aged 33, was infected with syphilis about eleven years before he was seen by me. He was treated for the disease continuously for two years, and after that period, every six months, for about six years. He continued his professional work, and was very successful in it, until about a year before I saw him, when he suffered from symptoms of what was thought to be neurasthenia. He was treated on this basis, and went out West, took active exercise on horseback. He improved somewhat, but then became considerably worse, and was finally brought to me in January, 1909, when he had distinctly the symptoms of paresis—forgetfulness, inability to concentrate, confusion of ideas, irritability, a good deal of mental depression, and certain almost delusional ideas regarding the way in which he was treated by his friends. Physically, he had distinct and characteristic dysarthria, tremors of the face and hands, exaggerated reflexes, and Argyll-Robertson pupils. The Wassermann test was positive. He improved a little for a time, but at the end of the following summer he was distinctly demented and delusional, and had all the characteristic physical symptoms of general paresis. These progressed, and he is now in the third stage of the malady.

The point of interest in this case is this: On inquiring carefully about the patient's earlier years, I found that five years before I had seen him, he had had an attack of mental depression, of a somewhat hypochondriacal type, such as so frequently ushers in paresis. This had occurred without special cause, and in a man whose habits were good, and who had inherited a sound constitution. I further learned that after he recovered from this depression, he had been a little different in temperament and character, a little more irritable and unreasonable, a little more egotistical and expansive than usual, his friends thinking that he was simply rather more conceited and difficult to get on with than before. But, in the light of subsequent events, it seems clear that these were the mental forerunners of his later attack, because when the later attack came on, all these characteristics were simply very greatly exaggerated. Thus, it seems that this attack of paresis can be traced back to a period of five years, during which time the patient achieved a really brilliant success in his profession, transacting his work effectively, and not suffering from any physical troubles whatever. It seems incredible that during all these years of successful professional work and social activity, he had any serious degenerative changes in the cortex of the brain, which changes are supposed to be necessary to enable one to make a diagnosis of paresis.

If the history of cases of paresis could be traced back in all instances, to the very remotest beginning, I believe that in a good many instances this prolonged preliminary period of slight mental perversion might be discovered, and, in this case I think that if treatment had been undertaken along proper lines three years before or two years before, the malady might have been kept in check.

The onset of a parasyphilis, occurring in persons who have had an infection, takes place in different ways as follows:

1. Acute symptoms of syphilitic exudates in the brain, ending promptly or later in paresis, or ending in cure, with or without mental symptoms, or ending in some deterioration with final serious cerebral vascular changes.
2. Acute mental symptoms, maniac or melancholic, ending in cure or paresis.
3. Tabetic and paretic symptoms, ending in taboparesis or in tabes with arrest of paresis.
4. Insidious mental and physical deterioration, ending in paresis.

The above initial conditions all may or may not end in paresis, depending on treatment, the constitution of the patient, and the intensity of the infection. Often they go on until nearly every symptom of paresis appears, yet they are even then arrested. The clinical phenomena, from the beginning to near the end, are produced by the same pathologic agent, and often can be controlled by treatment, even when the signs are ominously identical with early symptoms of general paralysis. This is what I mean by "cure of early paresis."

53 West Fifty-third Street.

THE SOY BEAN AS AN ARTICLE OF DIET FOR INFANTS

JOHN RUHRÄH, M.D.
BALTIMORE

The soy bean, sometimes incorrectly called the soja bean, has attracted attention from time to time as an article of diet for Americans and Europeans, but the attention has been ephemeral and but few if any attempts have been made to place the bean on a practical scientific basis as an article of diet. The composition of this bean and the facts that it is free from starch and of high protein content led me to try it as an article of food for young children and infants, and a preliminary report was made before the American Pediatric Society[1] in May, 1909.

The high protein content of this bean, about 25 per cent., probably accounts in part for the small amount of other nitrogenous food taken by the Chinese and Japanese, as the soy beans, and articles of diet made from them, are used in nearly every meal by the natives of Japan and China; and, when one takes into account the composition of the bean and the amounts eaten, it will be found that the Oriental gets a fair amount of protein daily. This general and continued use of the bean demonstrates conclusively that the protein of the bean may be utilized in the body in place of that of other vegetables and of meats. All sorts of foods are made from the beans, such as gruels, soups and porridges, but it is chiefly used in the East in the form of a cheese-like substance of which many varieties are made. It is eaten as a vegetable and picked green and used as a salad.

When one considers the American taste for meat and its great abundance in this country, there is little probability of the soy bean replacing meat by coming into general use, but it will be found of value as a source of protein when meat is contraindicated and especially when, as in diabetic diets, the patient tires of meats. As to its use in diabetics Dr. Julius Friedenwald and I expect to publish shortly a more or less extended report of cases showing its great value in this connection.

In the feeding of infants and of some young children one difficulty is to supply sufficient protein in a form in which it can be digested and assimilated. Mothers' milk is often not available, and the protein of cows' milk may not be suited, or cannot be adapted to the infant's digestion or, owing to certain diseases, may be contraindicated; and it is in these difficult and abnormal cases that the soy bean would seem to have a place.

---

[1] Arch. Pediat., July, 1909; abstr. in The Journal, July 10, 1909, p. 140.

To determine the true value of the soy bean in infant feeding it is necessary to have definite knowledge of the composition of the foods prepared from them, and some simple means of preparing food of definite composition at will. As soy beans are not available in most markets, and as their cooking is a tedious process, the possibility of making gruel flour from the soy bean was taken up with a firm which makes a specialty of making gruel flours, and after some experimenting a satisfactory flour was produced. This flour was then sent to a laboratory in New York for analysis, and the following results were obtained:

	Per Cent.
Protein (N. x 6.25)	44.64
Fat	19.43
Mineral matter	4.20
Moisture	5.26
Crude fiber	2.35
Cane sugar	9.34
Non-nitrogenous extract	14.78
Starch	None
Reducing sugars	None
Polarization normal weight due to optically active substance other than cane sugar (included in proteids and non-nitrogenous extract)	7.86°

The percentage of protein in this flour is almost one-third greater than the percentage of protein in the whole beans. This is caused by removing the coarse fibrous hulls which contain little protein.

A vegetable food of such composition certainly is remarkable when compared with round of beef, medium, which contains:

	Per Cent.
Protein	19.0
Fat	12.8
Moisture	60.7

Each ounce of this soy gruel flour yields about 13 grams of protein and 120 calories, and it can be used (1) as a gruel, (2) in broths, (3) in making biscuits or muffins. It may also be mixed with cereals, barley jelly, cream of wheat and the like.

Leaving out of consideration its use in diabetes both in adults and in children, the soy bean may be found of benefit in the following conditions as well as others:

In summer diarrheas and certain forms of intestinal disturbances a weak gruel (one or two level tablespoonfuls to the quart), made from the bean or, preferably, from the gruel flour made from the bean, will be found of great value. As a rule, it is well borne and digested and rarely causes either vomiting or an increase in the diarrhea. Barley or some other cereal should be added as suggested below. Later, when the food is to be increased, condensed milk or cows' milk may be added to the soy-bean gruel to advantage.

It is also of value as a diluent for cow's milk when used in the strength of four level tablespoonfuls to the quart (protein 1.4 per cent.) and this may be employed with condensed milk to advantage, greatly increasing the protein of the condensed milk mixtures. In many cases in practice condensed milk mixtures are of great service, but one serious drawback is the low protein content of the diluted milk. By the use of the soy-bean gruel this can, in a measure, be overcome. When this mixture is being used an occasional tablespoonful of orange juice should be administered as an antiscorbutic.

In cases of marasmus and in cases in which cow's milk mixtures are not well borne the soy-bean gruel may be added as a diluent of milk mixtures, and for backward, runabout children who are below *par* the addition to the dietary of soy broth or muffins may be tried.

The caloric requirements of the young infant are about 45.4 calories for each pound of body weight during the first three months of life; about 40.9 during the second three months, and about 36.4 calories to the pound during the second half of the year. The following table shows the approximate composition and caloric value of the gruels made from the soy-bean gruel flour. Each ounce contains about 13 grams protein and 120 calories.

Amount.	Protein. %	Fat. %	Sugar. %	Calories.
¼ oz. (1 level tablespoonful to quart)	.35	.15	.08	30
½ oz. (2 level tablespoonfuls to quart)	.70	.30	.15	60
¾ oz. (3 level tablespoonfuls to quart)	1.0	.45	.23	90
1 oz. (4 level tablespoonfuls to quart)	1.4	.60	.30	120
2 ozs. to quart	2.8	1.2	.60	240
3 ozs. to quart	4.2	1.8	.90	360
4 ozs. to quart	5.6	2.4	1.2	480
5 ozs. to quart	7.0	3.0	1.5	600
6 ozs. to quart	8.4	3.6	1.8	720
7 ozs. to quart	9.8	4.2	2.1	840
8 ozs. to quart	11.	4.8	2.4	960

If 6 level tablespoonfuls of the flour be used in making a quart of gruel, a satisfactory strength, 32 ounces would contain 19 grams of protein and 180 calories, being equal in protein to the same amount of average mother's milk, but containing about 400 calories less food value on account of the low fat and sugar content—a fact very important to remember in using soy-bean gruels. The caloric value of the gruel may be increased by adding condensed milk, sugar or cereals.

(1 oz.) 4 level tablespoonfuls of barley or wheat flour will add 100 calories.

(1 oz.) 4 level tablespoonfuls of oat flour will add 115 calories.

(1 oz.) 2 level tablespoonfuls of granulated sugar will add 100 calories.

(1 oz.) 3 level tablespoonfuls of milk sugar will add 100 calories.

Two ounces of sugar in a 32 oz. mixture = 6 per cent.

COOKING DIRECTIONS

Gruels.—A quart of gruel is made by boiling from 1 level tablespoonful to six ounces of the soy gruel flour in one quart of water for fifteen minutes, adding water to make up for loss by evaporation. Salt should be added to taste.

Composition.	Protein. %	Fat. %	Carbohydrates. %
One level tablespoonful to quart...	.35	.15	.08
One oz. (4 tablespoonfuls to quart)	1.40	.60	.30

These gruels do not thicken during cooking as they contain no starch, and readily settle on standing. This may be overcome by adding 1 to 2 heaping teaspoonfuls of barley, oat or wheat gruel flour before cooking, which will add from 0.6 to 1.2 per cent. starch to the gruels, and also slightly increase the percentage of protein.

Broths.—Add from 1 to 8 ounces of the flour to one quart of beef, mutton, veal or chicken broth and boil for 15 minutes, adding water to make up for loss by evaporation; or, boil the same quantity of the soy flour for one-half hour with one quart of water, to which has been added a piece of ham, bacon or salt pork to give flavor. Each ounce of the flour will add to the broth about 13 grams of protein and 120 calories, or in percentages, add 1.4 per cent. protein, 0.60 per cent. fat and 0.30 per cent. carbohydrates. A broth made with 6 ounces of the soy flour to the quart would be half as rich in protein and fat as steak.

Muffins.—To make muffins from the soy flour, take 1¼ teacupfuls of the soy flour, ¼ teacupful of wheat flour, ½ teaspoonful of salt, 2 eggs, 1 teacupful of sweet milk, 2 rounded teaspoonfuls of baking powder, and 1½ tablespoonfuls of melted, but not hot butter. Beat well together, adding the melted butter last, and bake in gem pans in a hot oven. This will make about 12 muffins which will contain about 150 grams of protein and which will yield about 1,800 calories of which the carbohydrates produce but 280.

The soy flour, being non-nitrogenous, requires the addition of some wheat flour in making muffins, as above. The mixture of wheat and soy flours in this formula will contain about 36 per cent. protein and 20 per cent. carbohydrates, against 14 per cent. protein and from 60 to 70 per cent. carbohydrates in gluten flour. The proportion of protein to carbohydrates is from 8 to 10 times as large in the mixed soy and wheat flour as in gluten flour.

I am indebted to Mr. M. F. Deming for assistance in getting a satisfactory soy flour made.

839 North Eutaw Street.

HYPERTENSION AND THE VALUE OF THE VARIOUS METHODS FOR ITS REDUCTION

JOSEPH L. MILLER, M.D.
CHICAGO

Until comparatively recently high blood-pressure has been considered an indication for active therapy, rather than a compensatory process, demanding treatment of the underlying condition. Unfortunately our knowledge of the primary factors responsible for the condition are still far from complete. We know that certain anatomic changes, as the vascular varieties of nephritis, sclerosis of the celiac axis or its branches or of the aorta above the diaphragm lead to or are associated with hypertension. In addition, however, there are cases of hypertension in which careful anatomic studies have failed to reveal the cause and which for the present we must designate as idiopathic. Janeway[1] has called attention to the frequency of hypertension without urinary findings. The view that hypertension is a compensatory process has been suggested by many, especially by Krehl,[2] and merits the most careful consideration. Hypertension in nephritis may increase elimination through the impaired kidneys, by forcing more blood through the organ; or marked sclerosis of the arteries in other organs may lead to increased blood-pressure in the effort to supply it with the required amount of blood. Some work has already been done on the effect on elimination of lowering the blood-pressure in hypertension associated with nephritis. (Kinnicutt,[3] Rossbach,[4] Bourginski,[5] Loeb,[6]) but the results obtained have been far from uniform. Loeb in his recent careful experimental work, has shown that lowering the blood-pressure 35 to 45 points, by nitroglycerin, leads to diminished elimination of water and urinary solids.

My observations have been confined to the direct effect on systolic blood-pressure of sweating, venesection and the various vasodilators. In a majority of the cases tested the urinary findings were of such character that chronic interstitial nephritis could be diagnosed. In a few patients the urinary findings differed not at all from normal or so slightly that it is possible kidney involvement was absent; since anatomically cases of this character not infrequently show extensive interstitial changes, however, a nephritis could not be excluded; for this reason no attempt was made to classify etiologically the nature of the hypertension.

* Headache.

The Stanton sphygmomanometer with wide arm-band was used throughout.

Several readings were taken before submitting the patient to the test, as it was found that the first reading, in case the patient was somewhat frightened or unaccustomed to the slight pain caused by the compression, might be 10 or 15 points higher than later readings. Since toleration for the vasodilatation is comparatively easily acquired, care was taken to select patients who had not recently received medication of this character. As some samples of sodium nitrite and nitroglycerin are inert, the activity of the preparation employed was first determined by animal experiment.

NITROGLYCERIN

There is considerable difference of opinion in regard to the proper dosage of nitroglycerin. Some have given enormous doses without ill effect. Stewart[7] gave at a single dose 5 grains, von Noorden[8] 5½ grains, Hochaus[9] 7 grains, Himmelsbach[10] 2½ grains. On the other hand severe collapse has resulted from comparatively small doses, as 1/120 grain (Loeb). Initial large doses should never be given, 1/100 of a grain is the usual dose, and this amount was selected for our tests. When a fall in pressure did not occur with this amount, 1/50 of a grain was given, but without any more effect than from the smaller dose. The nitroglycerin was given in the form of 1 per cent. alcoholic solution, dropped on the tongue from a graduated minim pipette. Seven of the ten patients selected reacted to the nitroglycerin by a fall in blood-pressure varying from 20 to 50 mm. One patient gave a transitory drop of 15 mm. but within five minutes the pressure was within five points of the previous level. The two remaining patients failed completely to react, the pressure remaining unchanged.

The first evidence of fall in pressure appeared, in all but one case, within two minutes and with one exception the maximum fall in pressure was attained within ten minutes and in the majority of cases within six minutes. This maximum was maintained for a few minutes, the pressure rising gradually until within thirty-five to forty minutes it had risen to within about 10 points of the original level. After this the rise was so gradual that in one case after the lapse of three hours it still was slightly below the normal level.

As a result of the medication two of the patients complained of severe headache. These two patients were only moderately affected by the nitroglycerin, the headache appearing during the recovery from the maximum fall. Only one of these patients had suffered from headache as a consequence of his hypertension.

In none of the patients, after the use of nitroglycerin, was there a rise in pressure, as has been reported by Loomis,[11] Hewlett,[12] and Dmitrenko[13] in man and by MacNidder[14] and Miller[15] and Matthews in dogs.

SODIUM NITRITE

Sodium nitrite, on account of its prolonged action, is considered by many more satisfactory than nitroglycerin. I employed it in solution in two-grain doses. Ten patients were studied; six reacted with a fall in pressure of 30 mm. or more; one 20 mm.; two 5 mm.; and one was unaffected.

The maximum drop was 75 mm.; in this instance the effect was transitory, as thirteen minutes later the pressure had risen to within 5 points of the original level. The first effect was observed as early as four minutes in one case; as a rule, however, not before six minutes. The maximum effect was obtained in from eight to fifteen minutes. The recovery to normal was more gradual than with nitroglycerin. Headache and other untoward symptoms were never observed.

Case 2, Table 3, is interesting, as the pressure continued to fall so that after the lapse of seven hours it was 70 mm. below the original level. The day following, the pressure fluctuated between 130 and 150 mm., although for several days previous to the test the pressure had been 200 mm. Following this the patient's pressure was taken daily; within forty-eight hours it reached 130 mm. and remained at this point during the two weeks the patient remained in the hospital. When the patient entered the hospital he was having uremic convulsions, the daily output of urine averaging 600 c.c. With the fall in pressure he became more comfortable, the convulsions disappeared and the urine averaged 1,700 c.c. daily. This case has been referred to in some detail for the purpose of calling attention to the rather decided and more or less permanent reduction in pressure that may take place in this class of patients. Another point of interest is the increased urinary output with the fall in pressure, although there was no special change in the fluids ingested, or in the loss through other channels. It is scarcely possible that the single dose of erythrol had anything to do with the permanent fall in pressure, as I observed a somewhat similar behavior in a patient in whom the erythrol could not possibly have been responsible. This patient (No. 9, Table 3) reacted in the ordinary manner to the drug, the pressure the day following having returned to the previous level of 200 mm. The pressure was then taken daily without material change in its height for a week, then without any treatment except rest in bed the pressure underwent decided change so that without a period of three days it fell from 200 mm. to 110 mm., where it remained two weeks, the patient feeling very comfortable. Then without apparent cause and without any change in the treatment the pressure rapidly mounted up to 222 mm. The patient became restless and complained of headache and developed uremic symptoms. Vigorous daily sweats were begun and within 10 days the patient was much improved, the pressure meanwhile having fallen to 90 mm., and remained approximately at this point during the patient's stay in the hospital. It is questionable whether the sweats were responsible for the fall in pressure, or whether it was due to some undetermined cause. These two cases are of special interest as they are the only ones in my experience in which prolonged hypertension has been followed by normal pressure, and corresponding improvement on the part of the patient. It certainly shows how conservative

* Headache.

ERYTHROL TETRANITRATE

Ten patients each received a half grain tablet of erythrol tetranitrate; the tablet was chewed and then swallowed. Five reacted by a fall in pressure of 30 mm. or more; two 15 mm.; two 5 mm.; and one was unaffected. The maximum fall was 110 mm.; this patient going into collapse, recovery taking place within fifteen minutes. The first effect appeared usually within four minutes, the maximum was reached within ten minutes or somewhat earlier than with sodium nitrite. The duration of the maximum effect was more prolonged then with sodium nitrite and the return to normal much more gradual. Six patients after receiving the medicine complained of severe headache, which in one instance continued for twelve hours. The headache appeared as a rule during the period of recovery from the maximum drop, came on suddenly and was intense in character. One patient had marked headache without reduction in the blood-pressure.

we must be in drawing conclusion in regard to the effect of any special line of treatment.

COMPARATIVE EFFECT OF THE VASODILATORS WHEN TRIED ON THE SAME PATIENT

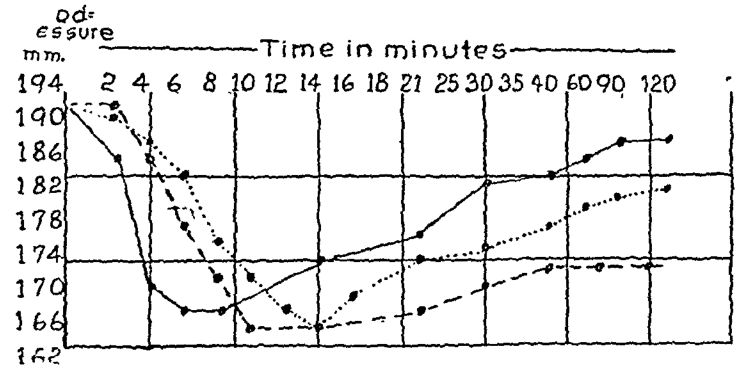
One patient, H. M. S. received on different days each of the three vasodilators. His pressure was not at all lowered by sodium nitrite, dropped 60 points after nitroglycerin and 110 points after erythrol.

Another patient, C. J., was not affected by nitroglycerin or erythrol but gave a drop of 65 points after sodium nitrite. A third patient, W. S., reacted by a drop of 30 points after nitroglycerin and 15 and 20 points respectively following erythrol and sodium nitrite. The patient who went into collapse after half a grain of erythrol was not affected by sodium nitrite.

The illustration shows the comparative action of the three drugs. This tracing was made by taking the average of each drug on the ten patients. This shows nitroglycerin most prompt in its action, erythrol second, sodium nitrite third. The degree of fall is strikingly similar in the three. Erythrol is most lasting in its effects as shown by the curve.

VENESECTION

The withdrawal of 300 c. c. or more of blood from the normal individual is followed by a transitory fall blood-pressure. Butterman[16] bled ten students, withdrawing from 200 to 480 c. c. and nine had a fall in pressure varying from 5 to 30 mm. Patients with hypertension do not necessarily react in the same manner. The effect on blood-pressure is dependent largely on the rapidity with which the blood is withdrawn. The first patient in Table 4 was bled slowly 500 c. c. from an arm vein, the blood-pressure remaining unchanged. One week later the same amount was withdrawn rapidly, a fall of 15 points resulting.



Comparative effect on blood-pressure of nitroglycerin (solid line), erythrol tetranitrate (line composed of dashes) and sodium nitrite (dotted line).

TABLE 4.—EFFECT OF BLEEDING ON BLOOD-PRESSURE

Case.	Blood-Pressure Before Bleeding.	Amount of Blood Withdrawn. C.cm.	Blood-Pressure After Bleeding.	
1	200	500	200	
2	190	500	185	
3	160	600	150	Two hours later 160.
4	185	500	170	Two hours later 180.
5	220	450	210	

As shown by Table 4 the effect of bleeding on blood-pressure was very slight and transitory.

SWEATING

In determining the effect of sweating on blood-pressure only those cases are reported in which the patients sweat profusely for at least 30 minutes. The method of inducing the sweat varied, being either by hot wet blankets, by hot bricks, or by hot air. The blood-pressure was taken just before the sweat was discontinued. As shown by Table 5, three of the five patients reacted by a reduction in pressure ranging from 13 to 20 points; in one of these cases four hours elapsed before the previous level was regained. In every instance the patient felt much better after his sweat; this was especially noticeable in the patients with uremic dyspnea, their breathing being much improved, even in instances in which the blood-pressure was not reduced. The relief obtained is not to be explained by elimination of water or urea, as the amount of the latter in a profuse sweat rarely exceeds 15 grains. A redistribution of blood is probably an important factor, the splanchnics being relieved by the better filling of the cutaneous vessels. This is analogous to what takes place in the Nauheim bath, in which the calcium and sodium salts produce distinct hyperemia of the skin, which in patients with poststernal distress is followed by relief; and percussion shows a reduction in the cardiac dullness, although the blood-pressure may have remained unchanged. Of greater interest than the effect of a single sweat was the result of daily sweats.

TABLE 5.—EFFECT OF SWEATING ON BLOOD-PRESSURE

Case.	Blood-Pressure Before Sweating.	Blood-Pressure After Sweating.	
1	160	140	Four hours before it reached previous level.
2	190	190	
3	170	170	
4	190	175	Two hours before it reached previous level.
5	185	172	

A number of patients were given one or more sweats daily for a period of two weeks or more, the blood-pressure being carefully taken each day but not immediately after the sweat. Here as with the other measures the results varied, in some the pressure remaining unchanged, in others a gradual fall in pressure took place. One patient in particular, who had been under observation for several years, the pressure during this time never falling below 210 mm. received daily sweats for two weeks, during the first five days, there was the usual transitory reduction after each sweat. From this time on, however, the pressure became permanently lower, the last five days never rising above 180 mm. previous to the sweat, and falling to 160 mm. after the sweat. Other cases with similar results could be cited. Rather prolonged benefit has resulted from temporarily relieving the heart of some of its burden in this way. It might be argued that rest in bed was instrumental in bringing about the improvement. The patient just referred to on a previous occasion was placed in a hospital on account of poststernal oppression and mild attacks of pulmonary edema was confined to bed and given the same general treatment but without the sweats. After two weeks pressure was the same as on entering. This indicates that his fall in pressure was probably due to the sweats.

The sweats, however, like all other measures, are not lasting in their effect, as within a short time the pressure returned to the previous level. Several of the patients sweated were complaining of poststernal oppression. This was largely relieved by a few sweats. It has been my experience that poststernal oppression, so-called uremic dyspnea, and mild pulmonary edema are relieved more uniformly by sweats than by any other measure.

---

[16] Butterman: Einige Beobachtungen über Blutdrucke bei Kranken, Deutsch. Arch. f. klin. Med., 1902, lxxiv, 1.

[17] Carter, H. W.: Clinical Observations on Blood-Pressure, Am. Jour. Med. Sc., 1901, cxxii, 854.

Attention should be called to some of the dangers of sweating. One of these patients was sweated in an electric light cabinet, at a hospital where the attendant was accustomed to turn on the cold spray immediately after removal from the bath. When the cold spray was applied to my patient, he complained of great post-sternal oppression and slight pulmonary edema. The day following it was requested that the blood-pressure be taken just before and then during the application of the cold spray, and it was shown that the application of the cold spray caused a rise in pressure of 60 mm. of mercury. Such measures are evidently decidedly dangerous. Another patient, who had a pressure of 220, for at least four years, shortly after being removed from the bath and while lying quietly on the cot in the hydrotherapeutic room suddenly developed left-sided numbness, transitory in character and continuing only a few hours. The pressure had been taken a few minutes before the attack and showed a reduction of 25 mm. The baths were continued with this patient, his pressure finally remaining around 190; he then developed repeated transitory hemiparesis with numbness. As the patient had been entirely free from attacks of this sort excepting for one rather marked hemiparesis five years previously, and as the attacks entirely disappeared after the sweats were discontinued, they probably were responsible for the disturbance. This can best be explained by assuming that the brain could be sufficiently supplied only through the narrowed vessels when very high pressure was maintained, lowering of the pressure causing cerebral ischemia with transitory hemiparesis. The same disturbances have also followed the use of vasodilators, indicating the necessity of careful further observation on this point and the possible danger of moderate reduction of hypertension.

Assuming that the lowering of high pressure is desirable, as it may be in certain cases, these and other observations have shown that it is attained with considerable difficulty. The vasodilators are all transitory in their action, and in some cases without any effect. Sweats and venesection are of value, especially the former. With the increasing tendency to assume that the hypertension is compensatory in character, the only rational method of treatment is to remove the cause; here we reach the borderline of our knowledge, and until better informed must consider increased elimination through skin and bowels and mental and physical quiet as the most satisfactory procedure.

CONCLUSIONS

1. In moderate doses active preparations of nitroglycerin and sodium nitrite temporarily reduce the blood-pressure in the majority of cases of hypertension.

2. Erythrol tetranitrate causes a more prolonged reduction in blood-pressure than nitroglycerin or sodium nitrite, but so frequently causes severe headache that its clinical value is much impaired.

3. Headache after any vasodilator does not mean that we are getting the physiologic effect in the sense that the blood-pressure is reduced, as the headache may appear independently of any change in pressure.

4. A patient's blood-pressure may be decidedly affected by one of these vasodilators and uninfluenced by another.

5. Occasionally the blood-pressure of patients with marked hypertension may show very marked fluctuations without apparent cause.

6. A single sweat reduces hypertension less than a moderate dose of vasodilators. If sweats are given daily, a rather marked reduction of pressure, lasting throughout the day, is observed not infrequently. When the sweats are discontinued the blood-pressure soon returns to its previous level.

I wish to express my thanks to the interns at Cook County and St. Luke's Hospitals for their interest and valuable assistance in these observations.

100 State Street.

DR. LYMAN SPALDING, THE FATHER OF UNITED STATES PHARMACOPEIA

J. M. EAGER, M.D.
Surgeon, U. S. Public Health and Marine-Hospital Service
PORTLAND, MAINE

In connection with the coming revision of the Pharmacopeia, a special interest attaches to the circumstances that led to the preparation of the first Pharmacopeia of the United States of America, and to the life and works of its originator and principal author, Dr. Lyman Spalding, who in January, 1817, at a meeting of the New York County Medical Society took the first decisive action toward uniting the medical societies and colleges of the different states for the purpose of devising a national pharmacopeia. That Dr. Spalding had long had the idea in mind is evinced by the fact that on May 21, 1808, he expressed before the New Hampshire Medical Society a dissatisfaction that there were so many separate pharmacopeias for different states. The regret was uttered in presenting as secretary of the society a copy of the Massachusetts Pharmacopeia which had been sent to him by Dr. John Warren, of Boston, a brother of Dr. Joseph Warren, killed at the battle of Bunker Hill. In the United States at that period and in the colonies previous to the union, the London and the Edinburgh pharmacopeias had been in use until certain of the states adopted special works on the subject. The importance of a legalized standard for substances used in medicine had always been evident from the standpoint of public health. So long ago as the year 1542, when the senate of Nuremberg sanctioned a work of the kind prepared by Valerius Cordus, the interest of governments in standardizing drugs was recognized. In England, May, 1618, a pharmacopeia issued by the College of Physicians was legalized as the London Pharmacopeia, and by the same act a separate charter was granted to the apothecaries for the sale of drugs and medicines, these substances having been previously handled by grocers as well as apothecaries. By the same law, the censors of the College of Physicians conjointly with the wardens of the apothecaries received authority to exercise supervision over apothecary shops so as to regulate the quality of drugs. It was by such an exercise of the law under intelligent control that, not only was the preparation of medicines of recognized value regulated in the interest of public health, but the banishment from apothecaries' shelves was ordained of many popularly cherished, substances of imaginary medicinal value such as calculi, crab's eyes, and moss from human skulls.

The Edinburgh Pharmacopeia was first issued in 1699 and the Dublin Pharmacopeia in 1807. These works together with the London Pharmacopeia were displaced in 1858 in Great Britain and Ireland by the British Pharmacopeia issued under authority of a provision in the Medical Act of the General Medical Council. Unfortunately, the efforts of Lyman Spalding in the

United States did not bring about a legal recognition of the Pharmacopeia by the Federal Government.

Many incidents in the life of the man who justly may be called the "Father of the United States Pharmacopeia" show that while his interest in professional work was broad extending to many branches of medicine he entertained from an early period of his career a special interest in chemistry and materia medica, leading naturally along the line of thought that culminated in the production of the work which has become a monument to his activity.

Lyman Spalding was born at Cornish, N. H., in 1775. His father was a farmer and a soldier of the colonial and the revolutionary wars. His general education was received at Charleston Academy, a few miles from Cornish. From 1787 to 1796, Dr. Nathan Smith, the distinguished physician and educator, was engaged in the practice of his profession at Cornish and was the family physician and preceptor of Lyman Spalding who studied in his office and accompanied him on his rounds visiting the sick. In 1795, Lyman Spalding went to Harvard Medical School from which he was graduated in 1797. Nathan Smith, also an alumnus of Harvard Medical School, traveled on horseback on one occasion from Cornish to Cambridge with Lyman Spalding. Another trip of the same sort Dr. Spalding made in the company of Philander Chase, afterward episcopal bishop of Ohio. After graduation, Dr. Spalding continued to assist Nathan Smith for three terms (1797, 1798 and 1799) in his lectures on chemistry and materia medica at the then newly established Dartmouth Medical School.

Dr. Spalding first settled for practice for four months at Walpole, N. H., in 1799. In June of that same year, an opening occurred at Portsmouth, N. H., where he remained until 1812. While at Portsmouth, he was favored with the use of the garden of Peter Coues, a sea captain who had once served on the famous battleship *Royal George*. Dr. Spalding was married in 1801 to Elizabeth, daughter of Captain Coues. An interest in materia medica led Dr. Spalding to plant poppy, lettuce and scutellaria. The opium and lactucarium he prepared were used in his own practice and the scutellaria was utilized in experiments for the cure of hydrophobia. William D. Peck, afterward professor of botany at Harvard, furnished the seeds from which the plants were grown.

In 1802, Dr. Spalding was appointed post surgeon at Fort Constitution, Portsmouth, which position he retained until 1812.

In 1809, Dr. Spalding went to Philadelphia and took a postgraduate course of four and a half months studying medicine under Benjamin Rush and under Dr. Barton, a professor of materia medica who was greatly interested in botany. He then went to New York, attended lectures for one month at the College of Physicians and Surgeons, returning to practice at Portsmouth in May, 1810. In October of that year he was invited to be professor of anatomy at the Fairfield Medical School, Fairfield, N. Y. This medical school originated from the Fairfield Academy started in 1803. Lectures on chemistry were begun in 1808 and medical lectures in 1810. Dr. Spalding was the first medical lecturer at the institution and, in 1812, when the school became incorporated as the College of Physicians and Surgeons of the Western Division of New York State, he was made president and professor of anatomy and surgery. As a preparation for teaching, and especially for teaching anatomy, Dr. Spalding had in 1807, previous to his visit to Philadelphia, acted as prosector, selected by Dr. Nathan Smith, to assist the well-known anatomist Dr. Alexander Ramsey in a course of lectures given at Dartmouth and lasting for several months. Dr. Spalding's work at Fairfield necessitated a trip on horseback every November from Portsmouth to Fairfield where he remained at the college for two or three months. At the time he was made president of the institution in 1812, there were from 50 to 65 students attending lectures there. During the winter of 1811-12, Dr. Spalding arranged to have Dr. George C. Shattuck, of Boston, his intimate friend, go with him to Fairfield as professor of medicine, but owing to the inconvenience of the long trips at an inclement season and the interference with his practice at Boston, Dr. Shattuck soon resigned the position though his friendly relations with Dr. Spalding continued as long as they both lived. Dr. Spalding's connection with Fairfield College continued until 1817 when, owing to political differences between the medical faculty and the college trustees, he resigned the presidency.

Before his disassociation from Fairfield College, Dr. Spalding went to New York in 1812 to enter practice being induced to settle in the metropolis because of the death of Dr. Edward Miller whose practice he hoped to obtain. Having made the acquaintance in 1797 of Dr. Samuel L. Mitchill, of New York, Dr. Spalding's introduction into New York medical circles was, through the kind offices of his friend, speedily and happily accomplished. Other papers of which he was the author having been favorably received by the New York County Medical Society, he decided in January, 1817, to broach his plan for a national pharmacopeia. The proposition was on the whole favorably received. Such opposition as was encountered the originator of the plan managed to overcome by surrounding himself with an efficient corps of collaborators, namely Thomas T. Hewson, Eli Ives, Elisha DeButts and Jacob Bigelow. He was himself chairman of the committee on publication of which the other gentlemen were members. In the formation of the committee on publication, Dr. Spalding journeyed one year from New York to Boston, a second year from New York to Philadelphia and a third from New York to Washington. In August, 1820, his son, L. D. Spalding, aged 10 years, carried the proof of the Pharmacopeia from New York, where his father was unavoidably detained, to Philadelphia delivering the papers into the hands of Dr. Hewson of the latter city. For his son's traveling expenses and board during the trip, Dr. Spalding charged the Pharmacopeial committee $13. The total cost of getting out the first Pharmacopeia, which ultimately appeared August 15, 1820, under the name of "The Pharmacopeia of the United States of America, 1820," was $2,235. The bill for printing was about $650. The book was announced as being issued by the authority of the medical societies and colleges. It was printed at Boston by Wells and Lilly for Charles Ewer, No. 51, Cornhill. The text was in English and also in Latin, it being explained by the publication committee that the use of Latin not only in the nomenclature but in all the essential parts of the work was adopted owing to the belief the book was thus rendered more intelligible to foreigners, and more useful in those districts of the United States where the French and German languages were spoken.

Immediately on the completion of the Pharmacopeia, Dr. Spalding proposed before the New York Medical Society a revision of the code of ethics; but before he could carry this plan through he met, in the spring of 1821, with an accident which ultimately brought to an end the activities of a brilliant life. The injury from which he suffered was caused by a box falling from a height on his head while he was walking on the street. Failing of relief under the care of his New York and Philadelphia colleagues, he went to Clarkston, near Tappan-on-the-Hudson, hoping to be benefited by the tranquility of a stay in the country. At that time, the body of the British Major André, buried in 1780, was disinterred. On exhumation of the body, Dr. Spalding called attention to the fact that the hair on André's head, which was shaved at the time of his execution, was of a considerable length. This phenomenon became the subject of a contribution made in 1906 to the *Chronique Medicale,* Paris, by Lyman Spalding's grandson, Dr. J. A. Spalding, of Portland, Me., to whom I am indebted for the main facts recorded in this brief biography, and in whose possession are many valuable and interesting documents relating to the first Pharmacopeia of the United States and the career of its talented originator.

Sept. 25, 1821, convinced that he had not long to live, Dr. Lyman Spalding sailed for Portsmouth where his relatives lived. Having made the journey by water, he arrived at his destination October 12. He died Oct. 30, 1821, and was buried in the North Burying Ground, Portsmouth, N. H.

INFECTIONS DUE TO THE BACILLUS AEROGENES CAPSULATUS

WITH A REPORT OF TEN CASES

JOHN BAPST BLAKE, M.D.
Visiting Surgeon, Boston City Hospital
AND
FRANK H. LAHEY, M.D.
Assistant Visiting Surgeon, Long Island Hospital
BOSTON

Many and varied were the conjectures in times past to explain the presence of gas in the tissues and hollow organs. By some it was thought to be the result of decomposition, and by others, atmospheric air, gaining entrance either through ulcers of the intestinal tract or lesions of the lungs. The former surmise, in a certain number of cases such as pneumaturia, etc., was probably true, but those cases in which the gas supposedly entered through an ulceration and manifested its presence in the tissues by emphysema, were without doubt cases of gas bacillus infection.

In gas bacillus infections also we probably find the explanation of many of the cases of air embolus written about by the very old writers, since it has been clearly established by Dr. Welch and others that gas, as the[1] result of post-mortem development of the *Bacillus aerogenes capsulatus,* frequently occurs in the vessels and heart cavities at autopsy.

HISTORY OF BACILLUS

The *Bacillus aerogenes capsulatus* was discovered by Dr. William Welch of Johns Hopkins and its description published in an article by Drs. Welch and Nuttall.[2]

It is usually the case that two investigators are at work at the same time, without cooperation, on any original observation. This was true in the discovery of B. A. C., and in 1893 Dr. E. Fraenkel published a description of the organism causing "gas phlegmon" which was identical with the organism discovered by Dr. Welch.[3]

In 1895, Goebel, ignorant of Dr. Welch's work, published a report on the bacillus of foamy organs.[4]

E. Fraenkel in 1893 first demonstrated the relation of B. A. C. to "gaseous phlegmon," the original work of Welch and Nuttall showing only its connection with gas in the blood. Later Dr. Welch repeated Fraenkel's experiments and confirmed his results.

Clinically, to Maisonneuve and Pirogoff is due the credit for the first descriptions of the disease. Maisonneuve, writing in 1853, called the disease *gangrène foudroyante,*[5] and Pirogoff, in 1864, acute gangrenous edema.[6]

Bottini[7] in 1871 first demonstrated the transmissibility of the disease and between that time and the discovery of its origin in 1891 there was much confusion, especially with the bacillus of malignant edema and Pasteur's *vibrion septique.* To-day in some of the text-books of surgery the description of B. A. C. and bacillus of malignant edema infections are confused. Even in some of the newer text-books B. A. C. is disposed of in a few lines which leave one with no clear idea as to its relation to other infections or the degree of danger associated with it. We cannot refrain from stating here that to really appreciate and understand how rapidly events may happen and with what fatal results in gas bacillus infections, one should see such a case as No II in our series.

Since Dr. Welch's first paper on the subject, except the discovery by Dunham in 1897 that the organism produces spores, little has been added to our knowledge of its bacteriology and practically nothing has been added to the clinical side or to our knowledge in the way of treatment. One of us (Lahey) has tried to limit the extension of the process in animals by the proximal injections of hydrogen peroxid but has done so only at the cost of the animal's life.[8]

The sites from which the B. A. C. have been recovered are many. In general way it might be said that the intestinal tract and the soil are the sources from which it is most consistently recovered. Dr. Hirshberg, working in the Johns Hopkins laboratory, recovered the organism from the intestinal tracts of rabbits, dogs and swine. In 1896, Dr. Walker at Johns Hopkins recovered it from dust collected in sweeping the floors, and at the same institution Dr. Harris recovered it from the contents of an old cesspool.

Dr. Welch reported in 1896 the bacillus recovered from a bullet in the head of the tibia, producing emphysematous gangrene, and E. Fraenkel reports the recovery of the organism from a splinter of wood in a case of tetanus.[9] One of us (Lahey) recovered it from the soil of the Boston City Hospital grounds, and in our series of cases it was recovered in a scalp wound resulting from a blow produced by the runner of a sleigh in midwinter on a snow-covered street. A case of B. A. C. infection following a lion's bite has also been reported.[10]

As Dr. Welch has stated, many cases have naturally been reported from Baltimore because of the interest in the subject there. As he also states, most of the writings are by Americans, and it is also of interest to note that practically all of these are by easterners. Few if any cases to our knowledge have been reported from any of the extreme western cities where traumatic lesions, in which soil infection would be likely, must be common.

---

[1] In the following lines B. A. C. will be used for *Bacillus aerogenes capsulatus.* We have in places substituted gas bacillus as a shorter term.

NOMENCLATURE

Owing to the confusion attached to this disease, the names by which it has been styled are numerous. The following are some of them: traumatic gangrene; *gangrène foudroyante;* acute mephitic gangrene; phlegmonous emphysema; gaseous phlegmon; emphysematous gangrene; fulminating gangrene; *gangrène gaseux.*

B. A. C. infection seems to us the best term to apply to this disease, because it takes its origin from the cause of the disease which must remain constant.

The other terms, such as gangrenous emphysema and phlegmonous gangrene, are not as satisfactory, since they take their origin from symptoms which may be present individually from a wholly different cause.

BACTERIOLOGY

The organism is a non-motile, anaerobic, short, thick bacillus, having a capsule, as its name suggests. It resists the decolorization of the iodin in Gram's stain and grows on nearly all media in the absence of oxygen. The gas formed in its growth is said to be of the following composition: hydrogen, 64.3, CO_2, 27.6, nitrogen 8.1 parts; it burns with a pale blue flame.

The organism grows on culture media in the presence of oxygen, as has been demonstrated by one of us (Lahey) at least twenty-four hours.

CHARACTER OF THE INFECTION

The gas bacillus makes its presence known always by a definite picture, the intensity of which is influenced by the severity of the infection and its situation.

The temperature is elevated as the process develops, sometimes directly after the injury or operation, sometimes late, depending on whether the process be of the acute fulminating type or of the late, delayed type of infection. There is nothing characteristic in the pulse, being elevated as a rule in proportion to the temperature.

The first appearance of the process almost invariably is the watery, blood-tinged discharge, not pus. On close inspection may be seen small bubbles of gas coming from the wound, or very slight crepitation is felt beneath the skin at the edges of the wound. Large or small blebs varying in size from a quarter up to four or five inches in diameter may be the first evidence, causing one to be suspicious of B. A. C. infection. These blebs are covered by skin at first dark red and shading into blue or green in appearance, later becoming distinctly blue in color, and are characteristic in B. A. C. infections. Their contents are fluid, which has the characteristic foul, sweetish odor of B. A. C. infections.

If one be suspicious of gas bacillus and well-acquainted with its odor, it sometimes may be thus distinguished before any other evidence is at hand. A culture taken will show the presence of the organisms and we have then a very early diagnosis.

Pain in all of the cases has been almost entirely absent, although since there is much edema there must be considerable pressure on the nerves. This is probably explained by the fact that the toxins of B. A. C. which have such a necrosing action may interfere with the conductivity of the various nerves in the tissues surrounding the process. Delirium is usually a late symptom, appearing after the process has become generalized and being present until death.

Nausea, vomiting and the constitutional symptoms so characteristic of other infections are not usually present in B. A. C. infections until the process has become very severe and as a rule beyond control. This seems explainable by the fact that the process extends mostly by direct extension and not through the lymphatics or blood channels. The lymph glands in pure infections are not enlarged and tender as in streptococcus and staphylococcus infections. There is no reddening and induration of the lymphatic channels and as a rule no development of fresh processes situated apart from the original infection. The process ascends a limb as a match burns with the lighted end held down, or, on the trunk, spreads out as a grass fire, extending between muscle planes, beneath peritoneum, along the path of least resistance, separating these layers by the distending action of the gas as it is formed.

Fascia, tendons and ligaments resist the infection strongly and as a rule are not affected by it. Muscle seems to be its most favorable site in which to flourish. At the original site of the wound we find the lacerated tissue soft, moist and of the consistency of pulp. Beyond this the tissues are pale and water-laden, containing small amounts of gas and apparently being prepared to assume the pulp-like consistency of the tissues at the original site of injury.

The foregoing description is that of an unmixed infection due to B. A. C. From this we may have the intermingling of the two processes—B. A. C. and staphylococcus or streptococcus infections—in any degree or proportion. The process may be a frank staphylococcus or streptococcus infection with occasional bubbles of gas and B. A. C. in small numbers, as in the lacerated wound of the scalp in this series, or may, starting as a simple ischio-rectal abscess, as has happened in the hands of one of our friends, begin to show itself as a B. A. C. process, rapidly changing from the predominance of the pus process to the complete overshadowing of it by the B. A. C. infection and resulting in death. In a case of this character the pus process remains local or practically so, with a tendency to recovery, while the B. A. C. process extends out into the tissues in the form of a practically unmixed process, which explains its severity.

In the cases in which the bacilli are limited to the wound, which contains a mixed process, it seems to us in cases we have seen much more amenable to treatment. But even in these cases the bacilli may remain locally present for some time, being active enough to produce gas, but not extending as is shown in Case 3.

TREATMENT

The treatment is always operative. Sometimes the operation will consist in the removal of stitches and allowing the wound to gape widely. Again it will require multiple incisions and sometimes we must resort to amputation. There are other things to do in the way of treatment but these are procedures which should be used as measures secondary or as adjuvants to the results obtained by one or more of the operative procedures. These secondary measures consist of frequent irrigations or spraying of the infected wound with hydrogen peroxid, the delivery of oxygen constantly into the wound from a catheter connected with an oxygen tank, or the submerging of an extremity in a constant soak.

First, to consider the indications for one or more of the operative measures. Concerning the opening of wounds widely there should be no doubt or hesitancy. In the presence of a fairly well-grounded suspicion the wound should be laid widely open and irrigated with hydrogen peroxid while a decision is made as to what more radical surgical treatment shall be instituted.

The other two methods, multiple incision or amputation, are not so easy to choose between.

Amputation must always offer the greatest chance of recovery, but also presents the disturbing thought that an extremity may have been sacrificed when multiple incisions might have accomplished the same result. On the trunk multiple incisions of course must be the only operation, no other being applicable.

In this series of ten cases four patients were treated by amputation, two died and two recovered. Two recovered under treatment with hydrogen peroxid, the wound being opened and treated locally; one recovered with oxygen delivered into the wound and one patient died with only local, non-oxidizing agents applied. In two cases treated by multiple incisions there was one death and one recovery.

Statistics as to operative results can be of little value since it is evident that the patients who recover under opening of the wound and secondary treatment with some form of oxygen would naturally be the mild cases, while amputation statistics would show many deaths, both because it is applied only in the extreme cases and because the operation itself, particularly when secondary to a compound fracture, etc., is of grave danger.

From this or from any other series of cases one cannot draw conclusions as to what is the best form of treatment in an individual case. In most cases it is safe to say that multiple incisions should be used only in the very early cases, and always with amputation in reserve if the former operation does not check the process. Amputation is practically always to be selected for the acute, rapidly extending process. While not always so, it is usually true that amputation must be done before the third day of the disease to be successful in saving life in a majority of the cases.

CASE REPORTS

CASE 1.—May 1, 1908, L., aged 27, single, a sailor; is said to have had arm run over by a freight car. Long lacerated wound on inner side of arm; elbow joint open; much laceration; radial artery pulsating. Wound cleaned, irrigated, loose fragments of humerus removed, drainage in front and back, sutured. Amputation refused by patient.

May 2, 1908: Dressing removed on account of bleeding, and wound packed.

May 4, 1908: Few bubbles of gas escaped from wound and crepitus beneath skin. Culture +.

Operation.—Arm amputated at junction of upper and middle third. Stump packed and left open.

June 1, 1908: Discharged, having had an uneventful recovery.

CASE 2.—March 30, 1907, K., aged, 51, was run over by freight car, causing traumatic amputation of left leg 4 inches above ankle, and right foot at mediotarsal joint. Both wounds full of dirt and grease. Chopart amputation on right and amputation at point of election on left.

April 1, 1907: Temperature has remained elevated, patient delirious; wound dressed; left leg shows typical sweetish, foul odor; bluish green discolorations over wound; blebs filled with bloody serum having very strong and characteristic odor; crepitus and gas bubbles from wound. Culture +. Patient removed to operating floor and reamputation at middle of thigh by transfixion. Following operation temperature fell to normal, but patient failed to recover from the shock of the second operation and died in two days. No organisms were recovered from wound and stump was apparently healing by first intention.

CASE 3.—March 20, 1906, L., aged 34, married, derrick fell on leg, causing compound fracture of tibia. Wound cleaned and put in plaster shortly after entrance; circulation of foot poor; moderate laceration of tissue.

March 21, 1906: Patient comfortable; circulation in foot still poor; plaster split.

March 22, 1906: Wound dressed; no evidence of sepsis, save bloody serous discharge of peculiar odor; afternoon temperature 103; pulse 130; bluish discoloration of entire leg; greenish area over upper part of tibia surrounding one of the wounds; gas escapes from wound on pressure; audible crackling sound of escaping gas on pressure. Culture +.

Operation.—Mid-thigh amputation. Subcutaneous tissues gangrenous.

March 24, 1906: Gas bubbles and positive cultures.

March 26, 1906: Few gas bubbles escape at each dressing on pressure.

March 30, 1906: Gas bubbles present up to to-day when, peculiarly, the temperature has reached normal.

April 19, 1906: Discharged. Convalescence uneventful up to this date.

CASE 4.—March 20, 1906, Mrs. W., aged 32, was admitted for gluteal abscess with deep fluctuation and suppurating abrasion. Incision and drainage; no free pus found but subcutaneous tissues apparently necrotic.

March 23, 1906: Wound dressed and edges found edematous and necrotic; gas escapes from edge of wound on pressure; culture +; patient delirious; former incision enlarged and again no free pus found.

March 25, 1906: Wicks have been changed; wound irrigated with hydrogen peroxid; no gas in tissues beyond wound, but general condition of patient failed, delirium came on and she died.

CASE 5.—Jan. 2, 1907, L., aged 52, stevedore, was struck by an electric car, knocked down, and sustained compound fracture at middle of left humerus. Cleaned, bones approximated and sutured.

Jan. 6, 1907: Wound dressed; large amount of bloody fluid (serum) evacuated. W. B. C. 17,400; temperature has remained 102 since operation.

Jan. 7, 1907: Dressed this forenoon; crepitus about wound and few gas bubbles from wound; wound widely opened and oxygen delivered into wound constantly. Culture +.

Jan. 10, 1907: Still slight crepitation and few bubbles; cultures ++.

Jan. 14, 1907: Uneventful recovery, except for a slight transient delirium.

CASE 6.—February 14, C., aged 27, single, teamster, was thrown from a pung on snow-covered street and dragged, runner striking head and causing long lacerated scalp wound. Wound full of hair and dirt. Wound cleaned and sutured loosely with rubber dam drain.

February 18: On the day following operation wound was dressed and a slight odor, sweetish and foul in character, detected. A few bubbles of gas came from wound. Smear from wound showed gas bacilli. Wound was laid open widely and irrigated frequently with hydrogen peroxid.

February 22: No gas from wound for past two days. Irrigations of hydrogen peroxid continued. Following this temperature came to normal and uneventful recovery ensued. Culture for gas bacillus negative on February 23.

CASE 7.—Aug. 5, 1906, L., male, aged 15, was struck by an automobile, causing crush of foot with large lacerations about ankle and lower leg. Wound cleaned, irrigated, curetted and sutured, with drainage.

Aug. 6, 1906: Dressed on day following operation (because of possibility of gas bacillus). Wound fairly clean; some discoloration of flaps distal to wound and similar discoloration between second and third toes; swelling somewhat increased.

August 7, 1906: Owing to foul, sweetish odor and discharge of bloody serum, multiple incisions were made about wound. Tissues were found to contain gas in small amounts and with but little extension. Culture +.

Following this, recovery uneventful.

CASE 8.—June 27, 1907, P., aged 56, painter, fell from staging (30 feet), sustaining fracture of lower end of radius and compound dislocation of ulnar. Large amount of dirt in joint. Extensive laceration of tissues. Wound enlarged, thoroughly cleaned and irrigated; rubber dam drain inserted and wound sutured loosely.

June 28, 1907: Plaster split; no odor; temperature 99.2 F. in forenoon; 101.8 in afternoon.

June 29, 1907: Foul, sweetish odor from wound; wound dressed; blue blebs, slight crepitation and gangrenous tissue found; removed to operating floor where multiple incisions were made. No gas was found but all of the tissues of the arm were pale and watery in appearance. Wounds were washed out with hydrogen peroxid.

June 30, 1907, patient died.

Case 9.—April 24, 1907, Mrs. H., aged 51, fell from a balcony on the outside of the house and received a compound fracture of the femur, with dirt in wound. Wound cleaned and sutured with drain and plaster spica employed. String attached to drain for removal.

April 26, 1907: Drain removed by pulling on string.

April 27, 1907: Foul odor of gas bacillus, elevated temperature and delirium. Wound dressed; gas escapes from wound; crepitation on palpation; characteristic blue blebs; odor so strong that it could be smelled throughout the ward. Operation advised; mid-thigh amputation; patient died on table.

Case 10.—X., a man, aged 66, was admitted to the Boston City Hospital for diabetic gangrene of the right foot; the condition had existed for five months and was complicated by a considerable sepsis; there was discoloration of the entire foot. At entrance, urine contained 3.5 per cent. of sugar and acetone bodies. Under a starch-free diet the urine became worse, but improved under a moderate diet. After two weeks mid-thigh amputation was recommended and accepted. It was done under spinal anesthesia, and was entirely free from post-operative shock. For sixty hours the convalescence was uneventful; then the temperature rose to 102 F., the wound being clean. Eighteen hours later there was a slight oozing of bloody fluid from the stump, and soon after this bubbles of gas were observed in the exudate, the stump becoming enormously swollen with extreme rapidity, discoloration and large blebs also developing rapidly. All sutures were removed and the wound left gaping, but the patient died within twelve hours from the time the gas bubbles were discovered.

A careful and thorough autopsy confirmed the findings made when the bubbles were discovered; the gas bacillus was found almost everywhere; the intestinal tract contained enormous numbers of them. The spinal canal did not show the slighest trace of irritation in any part. The precise route of contamination of the wound was not determined.

CONCLUSIONS

From the foregoing and other cases which we have seen, not here reported, it appears that in the majority of instances interference must be undertaken before the third day to make a favorable outcome probable. This is particularly true of the pure infections.

It is true, at least in this series of cases, that a lack of response to the infection in temperature is suggestive of a fatal result.

The grave danger of complete plaster-of-Paris dressing is only too well ilustrated in Case 9. The dressing in all soil-infected wounds should not be an impervious covering and should be one which makes constant observation of the wound easy.

Laborers must be particularly liable to this infection, because they are exposed so often in the course of their occupation to soil-infected wounds.

While the disease is relatively common it is certain that in only a small percentage of soil-infected wounds do gas bacilli develop.

What is the explanation of this? It seems to us that the condition is similar to that in the rabbit, whose blood is well able to take care of large quantities of living gas bacilli, injected into the blood-stream; but in this same rabbit, if a leg be broken and then injections made into the blood stream, a B. A. C. process may be started at once around the fracture. The same conditions seems true in the human being, that normal human tissue is able to successfully resist the presence of a considerable quantity of gas bacilli. While this cannot be proved by injection into the blood-stream, as in the rabbit, its corollary is established by the fact that many of the lacerated wounds acquired by workmen in the streets and from soil elsewhere must contain gas bacilli (since it is prevalent in the soil, as we know), yet but a small percentage of them show gas bacillus infections. This suggests that the tissues when not badly injured can and do by their own vital resistance render harmless the B. A. C. present.

This is further evidenced by the recoveries following amputation, even when some gas bacilli remains in the stump. What happens in this case is that the manufacturing site or nest of gas bacilli, that is the badly lacerated tissue at the point of fracture or injury, which is the culture media, is removed by the amputation at one sweep, changing the fight from one in which all the odds are on the side of B. A. C. (Since new bacilli are constantly sent out in increasing number from the nest at the point of injury to take the place of dead ones) to a contest in which conditions are reversed. Healthy tissue, even though it contain the gas and numbers of the bacilli in their process of spreading, is well able to successfully resist them, as is shown by several reported cases and the cases in this series, in which the patients have recovered although gas remained in the stump after amputation.

Furthermore, it seems but reasonable to suppose that in the cases infected with B. A. C. the blood retains a destructive, or at least a resistant, action to their presence. At autopsy we find large amounts of gas in the vessels, sufficient to produce fatal results from air embolus if present during life. Yet in B. A. C. infections we find gas only in the part affected, the process being always a local one, extending by direct progression. If the bacilli find their way so rapidly into the vessels after death it is but reasonable to assume that the reason that they do not do so during life is that conditions there are unfavorable for them.

How long the gas bacilli may live in the circulating blood we cannot say. Their presence in the circulating blood without producing gas has been definitely demonstrated at Johns Hopkins Hospital.[11] It seemed probable to us that Case 10 was infected through the blood from his own intestinal tract, from which enormous numbers of B. A. C. were recovered. This seems not at all improbable, particularly since Dr. Brewer of New York has demonstrated the liability of the kidney to septic infarcts when rabbits are fed bacteria and when one of the kidneys is exposed and only such gentle injury inflicted as would result from the tapping of the organ with the handle of a knife; and more so when it is realized that B. A. C. develop more easily and rapidly in the presence of sugar, this patient, No. 10, being a diabetic.

In Case 4 it would seem probable from the situation of the lesion that the infection might well have come from the intestinal tract by direct contamination in the feces, which we know as a rule contain numbers of gas bacilli. Knowing of another rectal case not reported, an ischiorectal abscess which was opened and became infected with B. A. C., resulting in the patient's death, we advise that all ischiorectal abscesses be protected from feces as carefully as possible.

That B. A. C. infections do not take place more commonly in this condition seems strange but is explained, we believe, by the fact that the abscess cavities are usually left widely open and that they are lined with a layer of granulating and walling-off tissues as a result of the abscess, both conditions being unfavorable to the development of B. A. C.

[11] Gwyn, N. B.: Bull. Johns Hopkins Hosp., 1899, x, 134; Cole: Bull. Johns Hopkins Hosp., 1902, xiii, 234.

In Case 3 it is interesting to note that temperature remained elevated as long as gas was present, although no other symptoms were apparent.

In the one case in which the process was mixed, Case 6, the infection was a mild one. This is in agreement with the majority of opinion that mixed infections are less severe than pure ones.

In these cases, five were compound fractures. The presence of soil in the wound was noted in six cases. The soil was that of a door-yard in two cases, from the dirt about a railroad in two, from street dirt in two, and probably in a third case. In one the injury was acquired on a street covered with snow.

Case 10 is interesting because of the existence of diabetes, as any medium is made more favorable for B. A. C. growth by the addition of sugar. Reasoning on this basis it would seem that diabetics should be more susceptible to the infection.

Plaster dressings were applied in three cases, two of which died. In both cases which died the process would have been discovered earlier had some other dressing than plaster been applied. If plaster dressings are applied they should be split, and in any injury in which B. A. C. would be likely to occur, that being any soiled and lacerated wound, the dressing should be thoroughly inspected for odor, watery discharge, emphysema, and particularly for bubbles of gas. This will mean inspection of the closest kind, for a small bubble of gas can easily escape the eye of one not on the lookout for B. A. C. infections.

To consider the B. A. C. infections as rare is a mistake. We have published in this article only unreported cases, but a much larger number of cases exists in the Boston City Hospital records. Many cases have been reported by other men and the condition certainly cannot be called uncommon. The complication must have occurred though unrecognized, or at least unpublished, in the practices of many general practitioners, particularly in the experience of those seeing many accident cases.

One should feel that the possibility of its occurrence is so definite that it should be guarded against. We are both of the opinion, from the cases we have seen, that it is liable to occur and will occur if given half a chance in a lacerated, soil-infected wound.

The best results are to be obtained, we believe, through prophylaxis, early diagnosis and prompt interference.

By prophylaxis we mean thorough cleansing of all lacerated or crushing wounds, careful cleansing and removal of dirt in soil-infected wounds, opening of the wound to the air as far as is feasible, instead of tight suture, even with drain, thus securing aerobic conditions which are unfavorable to B. A. C. The application of a dressing which allows the entrance of air to the wound as far as possible and dressings which may be easily removed for inspection of the wound, are also important. By early diagnosis is meant the careful watch for the signs before described, frequent cultures from the wound when in doubt and reopening of the wound where there is any question of gas bacillus infection.

By radical treatment we mean amputation in the fulminating type, with the stump left widely open; multiple incisions in the milder type, with careful and frequent inspection, so that amputation may be resorted to if the former treatment is not effective.

In regard to hydrogen peroxid and oxygen gas we can make no definite statement, but we do advise the use of the former in the stump after amputation and in the wound after the flaps have been opened.

We are of the opinion that B. A. C. infection is not a well-understood process in the minds of the average physician. We trust that we may have stimulated an interest that may result, should the infection occur in the experience of any hitherto unfamiliar with it, in its early discovery and successful treatment.

AN INQUIRY INTO THE CAUSATION OF NON-SPECIFIC URETHRITIS

JOSEPH HUME, M.D.
Lecturer and Clinical Instructor in Genito-Urinary and Venereal Diseases, Tulane University of Louisiana
NEW ORLEANS

Gonorrheal urethritis has held the attention of the medical profession so strongly from the earliest times that comparatively little interest has been taken in other forms of urethritis. I have endeavored in the following notes to classify certain of the non-specific urethritides, and to offer a hitherto unmentioned explanation of their origin, as well as that of certain forms of prostatic, vesicular, and vesical infections, the etiology of which have been more or less obscure. The material utilized as a basis for these observations has been obtained from 1,524 cases occurring in private practice.

I have rigidly excluded from the discussion all gonorrheal cases, all cases of chemical or mechanical irritation, urethritis ab ingestis, and all the rarer forms of urethritis attributed to general infective processes such as mumps and typhoid, or diathetic conditions like gout and rheumatism. It has also been necessary to exclude all cases of relapsing gonorrheal urethritis, and all cases of post-gonorrheal urethritis, i. e., discharges occurring in individuals who are gonococcus-free, but who may be subject to irregular attacks of subacute urethritis. Many rare and unique cases of urethritis reported by Guiard, Nogues, and others have failed to stand criticism because of a history of a previous gonorrhea, so that all such patients were excluded from this series. It is so common an occurrence to see the flare-up of a chronic post-gonorrheal urethritis without any apparent cause that it was deemed best to exclude such cases from the discussion.

I have in addition ruled out of consideration all cases in which there has been the slightest history or suspicion of gonorrhea unconfirmed by microscopic examination at the time; likewise all cases of patients who have been either injected, irrigated or instrumented. It was also thought advisable to exclude all cases of urethritis occurring in men over 40, owing to the possibility of an error in the history of the patient's earlier sexual experiences.

There remains for consideration a comparatively large class of patients who present themselves to the physician with a discharge following connection more or less definitely, or who accidentally notice a glueing of the meatus, or who complain of premature ejaculations or frequent night emissions. Again there are those who come to the physician with marked cases of prostatitis, vesiculitis, or cystitis, denying any and all probable antecedent cause, and in whom the examiner is unable to find gonococci, stone, stricture, etc., to account for the existing condition. It is this class of cases which I have thought deserving of a closer study with a view to a better understanding thereof.

It is exceedingly difficult to make a proper classification of the urethritides from the fact that any classification will differ according to whether the viewpoint be clinical, bacteriologic, or pathologic, but as it is important to have some working scheme, the one in the center of this page may suffice.

The etiology of the non-gonorrheal or non-specific groups is rather difficult to grasp at first, and it is only after a number of such cases have been seen and studied that the whole picture is clearly presented to the mind. The irregularity of the incubation period, the marked variation in inflammatory reaction, the changes in the urethra, and the varied microscopic picture of the discharges all tend to indicate differences too great to be explained by difference in virulence of organisms or suitability of soil. The fact is forced on one that there are two general types, at least, of non-specific urethritis; the one acute in character, following sexual congress *after a regular incubation period*, unattended by lesions indicative of chronicity, tending to run, like a true gonorrhea, a well-marked clinical course, and favorably influenced and easily cured by proper treatment; the other, chronic in nature from the start, sometimes noted after sexual congress, but with an incubation period markedly irregular—so much so that it cannot be said to have a true incubation period—presenting always urethral lesions which from their pathologic picture must have *taken months or years* to develop, and showing no tendency toward self-limitation, but characterized by resistance to treatment, and at times not amenable to cure. The former class I have termed cohabitative, sexual or infective urethritis; the latter auto-infective, or autogenous urethritis, both classes belonging to the nonspecific group of urethritides.

ANTERIOR URETHRITIS

ACUTE				CHRONIC					
Gonorrheal.	Non-gonorrheal.		Aseptic.	Gonorrheal.	Post-gonorrheal.	Non-gonorrheal.		Aseptic.	
	Cohabitative, sexual or infective.	Auto-infective, or autogenous.				Cohabitative, sexual or infective.	Auto-infective or autogenous.		

The acute forms of urethritis, non-gonorrheal in origin, are fairly infrequent, only 11 or 0.022 per cent., being encountered in 493 cases of urethritis of all types. The following case is quoted as being typical of this class.

Case 1.—*Patient.*—Male, white, aged 27, single. Last connection five days before examination (Sept. 22, 1908); previous one three weeks before. This forenoon he noted a slight white discharge. No pain or burning on urination.

Examination.—Healthy male. Moderately long foreskin, worn back. Meatus showed slight puffiness and hyperemia. Moderate grayish-white discharge (pus-cells in numbers, few epithelial cells, large number of Gram-positive cocci closely resembling gonococci with plain stain). First glass, hazy with shreds. Second glass, clear and no shreds.

Treatment and Course of Disease.—Zinc sulphate, 2 grains to the ounce, alternating with silver nitrate, 1/12 per cent., and daily anterior irrigations with 1 to 4000 permanganate of potash.

September 23: Discharge less. First, clear with fine shreds; second, normal; 28 French sound in anterior urethra. No infiltrations.

October 6: Daily ℞. Bare mucoid discharge. First, clear, few shreds. Second, normal.

October 18: No discharge for five days. First and second normal. Prostate and vesicles normal to feel and to microscope. Treatment stopped

October 25: No discharge. Urine normal.

December 2: Regular life. No discharge. Urine normal.

Such cases have an incubation period rather similar to that of a gonorrhea, five to nine days, but in the nonspecific case it is apt to be somewhat longer, as the infection is milder in character. In 11 cases the shortest period was four days, the longest twelve. These cases always show evidence of acute inflammation, as indicated by a reddened or puffy meatus, with a congested appearance of the urethral mucosa. The discharge is yellowish, but rarely frankly yellow, and only fairly profuse, seldom approaching the amount seen in gonorrhea. The discharge shows numbers of some organism usually alone, or else markedly predominant. The first glass of urine is more or less hazy with shreds, the second clear. An immediate urethral examination will not show any infiltrative changes. It must, however, be borne in mind that a urethral examination done at the close of such a case may possibly show fine infiltrations, whereas if done at the inception no infiltrations would be found. It is also to be remembered that such cases rapidly become chronic, and if first seen at such a time they may easily be misinterpreted. These cases are truly infective ones, they are acquired by direct contact during connection, and I will speak of them as cohabitative, sexual or infective.

The infecting organism was studied in 11 cases of this type. In 5 cases Gram-positive cocci alone were noted; in 5 cases bacilli alone were found, 4 Gram-positive, 1 Gram-negative; in 1 case both cocci and bacilli were found. The coccus is usually the *Staphylococcus albus*; the Gram-negative bacillus was the colon bacillus. The Gram-positive bacillus has not been recognized by name. It occurs as a diplobacillus, lanceolate shaped, with the rounded ends approximated.

It is unfortunate in this respect that more work has not been done to ascertain the pathogenicity of various organisms found in the female vagina. Gurd[1] has indeed recently investigated the flora of the female genital tract with great thoroughness, but no attempt was made to prove on anthropoids the pathogenicity of organisms found, which experiments, if looked into, might still further clear up this aspect of the subject, and prove of assistance in the future.

Closely analogous to such cases, on the surface, are those of patients who come into the physician's office purporting to have some acute urethral infection dating back to this or that connection. An examination shows little if any meatal puffiness or redness; the discharge, which is white and scanty, shows a variable and mixed bacterial character; the urine is clear with shreds or at the worst hazy with shreds, rarely definitely cloudy, as in true acute urethral inflammations. Such cases are often denominated "strain," or else attributed to masturbation, or to connection with an unclean woman, whatever that may mean. The patient is given some injection; in a few days the discharge has ceased, and the patient is considered cured, and the injection a cure-all. But if the examiner will make a careful urethral examination of such cases he will discover, in almost every instance, more or less marked infiltrations in the urethra, especially in the penile portion about the middle third. A urethroscopic examination will show the characteristic picture of a glandular or infiltrative urethritis. These facts being so, it must then be granted that this "new" case is not new at all, but merely a new observation on the part of the patient of an infective process which must have been already established for some time to produce such marked pathologic changes in the urethra itself.

---

[1] Gurd: Jour. Med. Research, xviii, No. 2.

It is interesting to glance at two lines of argument which support the view that such urethral conditions are very often unobserved until some particular suspicion or coincident effect calls the patient's attention to the slight discharge; first, the overwhelming proportion of such cases among medical students, who are notoriously given to a minute inspection of both subjective and objective phenomena; second, the statement of Waelsch[2] who refers to an intractable form of non-specific urethritis which he has found only in medical men. There is surely no reason why medical men should have a monopoly of a distinct urethral disease; it is, however, certain that they are apt to be better observers and more critical of their own bodies than the ordinary layman, so that what would pass as insignificant with the latter would not so easily escape the self-examination of the former. Out of 59 cases of urethritis in medical students in my series 14, or 23 per cent., were non-specific in nature, whereas out of 434 cases in private practice only 27, or 0.062 per cent, were non-specific. And of these 27, 9, or one-third, were in physicians. Roughly speaking, non-specific urethritis is discovered four times more frequently in medical men than in laymen, simply because of the mild disturbances it causes. Often this condition can be found in patients who are not suspicious of any urethral trouble, but who consult us for varicocele, circumcision, etc., and I have noted it in men who have never had sexual connection, or in others who have always used condoms.

The so-called incubation period of this type of urethritis is naturally vague and uncertain, and as stated in 30 cases was found to vary from one to thirty days. The meatus rarely presented signs of acute inflammation. The discharge is slight, grayish or white, with varied bacterial contents, never presenting large numbers of one organism either alone or decidedly predominant. The first glass of urine is usually clear, but shows fine floating shreds; the second glass is normal. And, to complete the picture, an immediate urethral examination will show more or less marked infiltrations. The prostate may likewise be involved, though presenting no symptoms. It is to be noted that though chronicity is the marked characteristic, yet these cases, with the necessary concomitant conditions, may show temporary "flare-ups." In addition, it is perfectly possible for a patient to acquire the first type described, acute non-specific urethritis, on a urethra already damaged in the manner outlined above.

What the origin is of this low-grade infection, and how it is brought about are natural questions that arose during a study of the cases. After many factors were looked into and cast aside, it appeared somewhat probable that perhaps a long foreskin with its necessary accompaniment of moisture and dirt might account for the condition. A glance at the following tabulation shows the condition of the foreskin in 30 of these cases.

Long foreskin	18
Medium foreskin	5
Short foreskin	2
Circumcised	1
Not noted	4

To ascertain the normal condition of the foreskin in childhood, as possibly bearing on the chronic forms described above, 91 successive male children were examined at the Touro Infirmary and Charity Hospital, through the kindness of Dr. King Logan. Their ages were from 2 months to 12 years. The following facts were noted.

Foreskin (91 Cases)	
Phimosis	15
Long	69
Medium	1
None	6

Meatus (59 Cases)	
Reddened	34
Normal	12
Not seen	4

Adhesions of Foreskin, 56; Discharge from meatus, 9.

Almost without exception the prepuce is long, often phimotic, adhesions are present, and there is about the meatus spreading peripherally over the glans penis an area of congestion, more or less red and of a width approximately dependent on the extent of the adhesions. When the adhesions are broken up this superficial congested area disappears rapidly as a rule. The statements of many pediatric specialists concur in the belief that a long foreskin with marked adhesions is the overwhelming rule in the male baby. I was unfortunately unable to find in the young male a definite case of marked urethral discharge, non-gonorrheal, but the conditions were not favorable in that most of the children had just urinated recently, thereby preventing any accumulation of discharge. I found, however, several cases, 9 in number, in which there was slight urethral moisture containing epithelial cells, few pus cells and bacteria; indeed, it cannot be hoped to find a definite non-specific urethritis except once in many hundred cases. In this connection it should be borne in mind that an adult may show a medium foreskin which when he was a child would have been a long one.

This condition of a long foreskin encourages heat, moisture, and uncleanliness around the meatus, all favorable factors for germ development. Jungano[3] recently, and many others before him have shown how many organisms are habitually present about the meatal lips and the glans penis, in addition to those in the normal urethra; with such factors tending to encourage germ development and urethral congestion it is quite possible and highly probable that many urethras are not able to withstand bacterial invasion and become permanently infected with organisms of low pathogenicity. Likewise it is not unlikely that some of the obscure joint lesions and kidney infections of childhood may owe their origin to such a source. A consideration of these facts makes it rather probable that in the young male all the conditions are present which allow a local infection to start; that in some cases it does so start, is unnoted, and becomes extremely chronic and slowly produces changes in the urethral mucosa, submucosa and glands. Later on after puberty, following intercourse and the attendant alcoholic irritation, the passage of very acid urine, etc., the mind becomes suspicious, attention is centered on the penis, a slight discharge is found, and the patient presents himself to the physician for an examination.

---

[2] Waelsch, L.: General Syphilis without Primary Manifestation and Professional Syphilis in Medical Men, München. med. Wchnschr., April 27, 1909; abstr. in THE JOURNAL A. M. A., June 5, 1909, lii, 1895.

[3] Jungano: La flore de l'appareil urinaire normale et pathologique, Paris, 1908.

A careful examination of such a patient discloses the condition described above, for which I have tentatively suggested the term auto-infective or autogenous urethretis, by which is meant the type which invariably develops spontaneously in one's self, in contradistinction to that variety which follows intercourse, therefore designated cohabitative, sexual or infective urethritis. This form is much more common than the sexual variety, being noted 30 times, or 0.063 per cent., in 493 cases of urethritis; it is about three times as frequently met as the sexual or infective type. A striking fact is that I have never yet noted its occurrence among Jews, who are without foreskin practically from birth.

To illustrate this condition more fully the following case is quoted as typical of this type of urethritis:

Case 2.—*Patient.*—White, male, aged 20, single; denied all previous venereal diseases. Discharge noted morning of day of examination (April 24, 1908); some burning on urination noted day before. Last connection eight days before examination; previous one four weeks before.

Examination.—Healthy male; long foreskin; meatus medium red, perhaps a little puffy. Slight watery, grayish discharge, showing pus, epithelial cells, few cocci and diplobacilli. First urine, clear with few fine shreds; second, normal.

Treatment and Course of Disease.—Anterior irrigation with 1 to 4000 potassium permanganate.

April 25: Barest moisture (pus and epithelium, very few cocci and bacilli). First, clear, with few fine shreds; second, normal. Treatment, anterior irrigation with 1 to 4000 potassium permanganate.

April 26: No moisture; first, clear, with 2 to 4 shreds; second, normal; 23 French sound showed very numerous and marked infiltrations, especially in the first three inches of the urethral canal.

June 2: Patient said that he was well and discontinued reatment. Urine normal, both glasses.

The question as to whether the organisms of the auto-infective or autogenous type of urethritis are infective for other urethræ is interesting, and I have found one case which is very suggestive. Two young men, never before infected, A and B, had connection with the same woman on the same night, A two hours before B. B came into my office a few days later, October 8, 1908, with a fairly profuse yellowish discharge, showing a Gram-positive diplobacillus, lanceolate-shaped, in great numbers. The first urine was hazy, with shreds, the second, normal. His urethra and prostate were normal, and the case ran the typical course of an anterior urethritis, being cured in fifty days. He told me of A, and I advised him to tell A to watch out for signs of infection. A came to me eleven days after B's first visit, October 19, 1908. For two days he had noted a slight smarting on urination. He presented a long foreskin, and a medium red meatus, with a slight white discharge containing epithelial and pus cells, and large numbers of lanceolate-shaped, Gram-positive diplobacilli, with various other urethral bacteria. These diplobacilli were similar to those found in B's case. The first urine was slightly hazy, with numerous shreds, the second normal, prostate normal. Three days later his urethra was examined, and marked anterior infiltrations found. The patient was treated for three months and a half before he was cured. A stated that he would never have thought of any trouble unless he had been cautioned by B.

The prognosis of the cohabitative or sexual form of urethritis is good, and as a rule the patients are easily cured. Many of the so-called gonorrheas which are cured by a few injections are unquestionably unrecognized cases of this type. The prostate may occasionally become involved, but other complications are rare; I have, however, seen epididymitis occur.

The most effective treatment for this type consists of injections of silver nitrate, 1/12 per cent. to ⅛ per cent., increasing in strength as the inflammatory process declines, combined with daily irrigations of potassium permanganate in ascending strengths. The proteid silver salts are good, but I prefer to use the nitrate as giving better results. As the case progresses toward a cure an astringent injection is alternated with the silver, until the latter is finally discarded. The duration of treatment varies from three to four weeks, the longest time being about three and a half months in cases in which the prostate is involved. There are some forms, however, due to an infection with a slender bacillus, which appear to be more amenable to the action of the zinc salts, perhaps comparable to the results of zinc in conjunctivitis due to the Morax-Axenfeld diplobacillus.

On the other hand, the prognosis of the auto-infective or autogenous form of urethritis is not so favorable. The infective process has been going on for many months or years, inflammatory changes have become well marked, and there is often a well-developed fibrosis in localized areas of the urethra. In addition, the prostate is often infected, and it may, and usually does take months to effect a cure; in fact, in many of these cases it is impossible to restore the mucosa and submocosa to a normal state. Too often a slight urethral moisture remains, or else recurs several months after treatment has been stopped, and prolonged observation of such patients for several years has led me to believe that few if any are positively cured, a slight discharge containing pus cells being present if the urine is held for six or eight hours.

This type of cases is best treated along the following lines: circumcision; massage of the prostate, followed by intravesical irrigations and hot rectal douches, if the prostate be involved, as shown by the presence of pus in the prostatic secretion rather than by digital examination of the gland; dilatation of the urethra in combination with urethral irrigation; injections. Of the latter silver nitrate in strengths of 0.25 per cent. to 0.5 per cent. offers the most hope in the severe cases; it should be kept up for one or two weeks, then giving place to a course of urethral dilatation. It is advisable to give a long course of treatment subdivided into short periods with an interval of rest in between. Time is an essential element in the treatment to enable the infiltrations to soften and be absorbed. Ointments applied locally to the urethra would apparently be useful, but I have not found them very efficacious; in sluggish cases, however, it is well to try ichthyol or balsam of Peru, in full strength or with equal parts of lanolin.

I would again insist on the fact that many such patients may be apparently cured; they may have normal prostate, normal urine, no discharge, and a urethra without perceptible infiltrations; yet if observed for six to eighteen months they will almost always show a slight discharge, a few shreds in the urine, and infiltrations of the urethra now again perceptible, indicative of the fact that the infecting agent has not been entirely eradicated. Again, there are other cases, belonging to the same general class, in which even a temporary cure cannot be effected, a slight discharge and marked infiltrations persisting in spite of all treatment. I have kept such patients under treatment and observation for two years and more, until I was convinced that with our present methods a cure was impossible.

In many cases belonging to this class the patients are made neurasthenic, and spend many hopeless years because this fact is not known. With experience it does not take long to ascertain the possible limit of improvement of each case; when this point is reached the patient should be told the truth as to the condition, and he should be advised to discontinue the treatment, but to report at intervals for an examination.

I have purposely avoided any discussion of the aseptic type of urethritis; there is no doubt of its existence; it is always associated with infiltrative lesions of the urethra, and is probably dependent on deep glandular infections. It is most probable that when more work has been done on the anaerobic flora of the urethra we shall have a much better understanding of this class of cases.

It is highly probable that the urethral condition which is brought about by the form of auto-infective or autogenous urethritis will readily account for the variability which so many cases of gonorrheá show. Considering first cases of gonorrhea only, and for the sake of clearness those limited to the anterior urethra, it is well known how many differences they show in their clinical course; some heal kindly, and complete resolution follows; others tail off in a most exasperating chronicity, though gonococcus-free; others flare up with acute exacerbations time and again. If, however, one comes to realize that these first anterior gonorrheas occur, some on a virgin soil, others on a field already damaged by less virulent but none the less persistent organisms, it will soon be clear that the virulence and chronicity of the gonorrhea may well be determined by the presence or absence of pre-existing inflammatory changes in the urethra. I have therefore come to the belief that the variation from the normal which must exist in many urethras accounts for the chronicity and tediousness of many a first gonorrhea.

There are certain cases of prostatitis and vesiculitis which occur in patients who give no history of venereal infection, or of instrumentation, or of any other source of contamination. Such an infection must be explained, as some do, as a result of normal masturbation, or as a descending infection which unaccountably fastens on the prostate alone, leaving the rest of the genito-urinary tract untouched, or as a direct infection from the rectum or blood-stream, or, finally, on the assumption of a low-grade ascending infection, which, giving little discomfort to the patient, was unnoted or passed over by him at the time. I firmly believe, as a result of clinical observations, that many such cases follow some antecedent urethral infection, which becomes extremely chronic, dies down or out, but not until after it has infected the sexual glands. It is certainly common enough in gonorrhea to see an infected prostate with normal urine and no symptoms of trouble. It is pretty certain that some cases of cystitis in women are brought about by a direct ascending infection from the vagina. I have noted involvement of the prostate in 6 out of 11 patients who presented themselves for circumcision or varicocele with no urinary symptoms whatsoever; in these cases the urine was clear, symptoms were entirely absent, and the condition was found only by routine examination of the urinary tract as a prelude to treatment. This form of infection must be taken into account in considering the etiology of senile hypertrophy of the prostate.

The following cases are quoted in detail because of their instructive features in this connection:

CASE 3.—*Patient.*—Male, white, aged 24, single; never had stayed with a woman in his life. In the summer of 1904 he had an attack of malaria, and at that time noted burning on urination and a thick white discharge. Shortly after this he was laid up with a slight epididymitis. He had had no

TABLE 1.—COHABITATIVE AND AUTO-INFECTIVE TYPES CONTRASTED: 4 CASES EACH

Age.	Foreskin.	Meatus.	Incubation.	Discharge.	Bacteria.	Urine.		Urethra.	Prostate and Vesicles.	Treatment.	Duration of Treatment.	Result.	Remarks.
						1" glass.	2" glass.						
					COHABITATIVE, SEXUAL OR INFECTIVE								
21	Medium....	Puffy and hyperemic.	5 or 21 days.	Medium yellowish	G. P. coccus..	Hazy with shreds.	Normal.	Normal.......	Normal.......	Injections and irrigations.	26 days.....	Cured	
19	None........	Pink and puffy.	4 days..	Medium yellowish.	G. P. diplobacillus.	Hazy with shreds.	Normal.	Few fine infiltrations.	Normal.......	Injections and irrigations.	30 days.....	Cured	Circumcised 6 years ago. Few fine infiltrations noted at end of case.
19	Short.......	Congested....	7 days..	Medium, white, watery.	G. P. coccus..	Hazy with shreds.	Normal.	Normal.......	Prostate badly involved, much pus.	Massage, injections and irrigations.	2½ months..	Cured	One year later. No discharge; 1" and 2" glasses normal.
22	Not noted..	Pink and puffy.	12 days.	White..........	G. P. coccus..	Cloudy with shreds.	Normal.	Not noted....	Normal.......	Injections and irrigations.	23 days.....	Cured	*Staphylococcus albus* in pure culture. All connections for past 4 months with same woman.
					AUTO-INFECTIVE OR AUTOGENOUS								
26	Very long..	Reddened....	....	Mucoid..........	Bacilli and cocci.	Clear; few shreds.	Normal.	Marked infiltrations.	Normal.......	Dilatations and irrigations.	8 weeks.....	Cured	Never with a woman in his life.
20	Long.	Slight pinkness.	8 days..	Watery, yellowish.	Diplo-bacilli and cocci.	Clear, with shreds.	Normal.	Marked infiltrations.	Not noted....	Dilatations and irrigations.	4 days......	Cured?...	Discharge ceased — certainly not cured.
22	Very long..	Puffy, not red.	2 or 9 days.	Watery, white...	Rare cocci...	Hazy with shreds.	Normal.	Dense infiltrations.	Not noted....	....	....	....	Not treated.
19	Long.	Normal.	3 or 17 days.	Scant, white......	G. P. cocci, diplococci and bacilli.	Clear, with shreds.	Normal.	Marked infiltrations.	Normal.......	Injections, irrigations and dilatations.	3½ months.	Cured	Examined 2 years later; 1" and 2" glasses normal.

treatment except internal medication. At the time of examination (March 13, 1905) the discharge and burning continued; he urinated every two hours in the day and twice at night. Erections were good and night emissions frequent.

Examination.—This showed a long, adherent foreskin, chronic balano-posthitis, and masses of smegma could be squeezed out of pockets in the preputial cavity. The meatus was red and contained a thick grayish-white discharge showing pus, cocci and bacilli. The right globus minor was somewhat thickened and hard. First, second, and third glasses were cloudy (pus) with shreds. Prostate was a little enlarged, increased in density, and tender; right vesicle thickened, left normal. Secretion from prostate and vesicle was dirty white, showing under the microscope all pus with cocci.

Treatment and Course of Disease.—Patient was circumcised, many adhesions being broken up. He was treated for five months and discharged cured. He was reexamined in June, 1908, three years later; no discharge; meatus normal. Urine, both glasses normal. Prostate and vesicles normal to feel; secretion white, containing spermatozoa, lecithin, granule cells, with rare leucocytes.

January, 1910: No trouble. No discharge. First and second glasses normal.

Case 4.—*Patient.*—Male, white, aged 26, single; never had stayed with a woman in his life. He complained of frequent night emissions, two or three per month. He had worried about them only lately, and then only because he did not understand them.

Examination.—This showed a very long foreskin, a congested, purplish area about the meatus with some redness of the urethral mucous membrane; slight watery discharge showing epithelium, pus, few cocci and bacilli. First urine had mucoid haze with shreds; second clear. Prostate showed involvement to feel and on examination of secretion by microscope; 20 French sound showed very dense, large, well-marked infiltrations in penile urethra.

The patient was treated and cured.

A thorough study and understanding of the above facts will lead one to a more definite comprehension of the etiology and pathology of non-specific urethritis, and will point the way to a more exact knowledge of the causation and development of certain obscure cases of genitourinary infections; at the same time it will enable one to explain logically the exceeding variability in the reaction of certain urethrae to gonorrheal invasion.

In Table 2, 41 cases are tabluated as regards special points to which attention should be called:

CONCLUSIONS

In closing I feel warranted in offering the following conclusions:

1. Non-specific urethritis, acute and chronic, is a definite clinical entity.
2. Many of the non-specific cases of urethritis are not of a sexual origin.
3. A long foreskin may be the possible starting-point of those types of non-specific urethritis not due to connection, because it produces urethral congestion in early life, and favors moisture and germ growth.
4. The variation and chronicity of many cases of gonorrhea are due to pre-existing urethral changes of a non-specific character.
5. The existence of chronic non-specific urethritis offers a feasible explanation of the origin of many cases of obscure prostatic or vesicular infection.
6. The practice of circumcision should be encouraged as a means of preventing autogenous urethral infection.

ANIMAL EXPERIMENTATION IN RELATION TO PRACTICAL MEDICAL KNOWLEDGE OF THE CIRCULATION*

JOSEPH ERLANGER, M.D.
MADISON, WIS.

IN THREE PARTS

INTRODUCTION

There are but two paths along which the advance of medical science and art can be pressed; they are observation and experiment. The two lead to the same goal; both are beset with difficulties or even with obstacles which for the time being are, or may even forever be, insurmountable. In any case it is essential, in order to ascertain beyond peradventure that either of the paths has led us to our goal, to show that the two lead to the same place. Still, to have threaded one of the paths successfully usually assures an easy and early approach by way of the other. Indeed, the opening up of one path often leaves the finding of the other merely the matter of a single trial. When this is the case we are apt to lose sight of the fact that actually the goal has been reached by an advance pressed along both pathways.

The bearing of these remarks on the subject-matter of this paper becomes obvious when it is recalled that as subjects of observation and experiment the medical investigator employs both man and the lower animals. The method of pure observation may be employed in the study of both, whereas man can be employed as the subject of an experiment only with his full knowledge and consent and in such a way as to inflict neither bodily discomfort nor pain, except the not infrequent instances in which the experimenter himself serves as subject of the experiment. But experiments of the kind that can be made by the experimenter on himself are, for obvious reasons, limited in number. There remains, then, a whole host of experiments that must be performed on the lower animals, if medical knowledge is to be advanced. This statement is true, it matters not what view we may hold as to the justifiability of experiments on animals; it is nevertheless called into question by certain misinformed or misguided persons who argue that experiments with the lower animals cannot serve to throw any light on the functions, either normal or abnormal, of the organs of man. This objection, though untenable as it stands, contains an element of truth. It is true that inferences, based on animal experiments, as to the functions of the organs of man must be carefully guarded. When, however, they are checked by critical observation of, and painless experiment on, man, inferences from animal experiments have, we believe, led us to the greater part of our practical medical knowledge and the part which is considered the most valuable.

---

* This paper is one of the series prepared for and reprinted by the Council on Defense of Medical Research of the American Medical Association for circulation among the public. Fourteen of these pamphlets are now ready, taking up the relations of animal experimentation to ethics, diagnosis, cancer, vaccination, the live stock industry, tuberculosis, typhoid, dysentery, plague, rabies, surgery, internal secretions, the circulation of the blood, protozoan tropical diseases, etc.

Scientists, then, are all agreed that the findings of the laboratory must be in full accord with the matured conclusions of bedside observation if they are to be entitled to enrolment in the category of established medical truth. Furthermore, it is equally true that bedside observation can lead to the truth only when it is checked by experiment, which in this case may, however, be made for us by the slow and precarious methods employed by Nature. It is just at this point that it becomes difficult to determine what part of medical advance along any line is due to the achievements of the animal experimenter and what part to keen observation, at the bedside, of experiments performed by disease and trauma. However this may be, all who are in a position to know are of the opinion that they are mutually helpful.

Indeed, they are mutually helpful in more ways than one. A very large part of the best clinical observation has been, and is being, made by clinicians who have had the opportunity of witnessing and performing animal experiments during their student days, or who have actually been engaged in research involving animal experimentation. The fruit of clinical observation naturally depends very largely on the attitude of mind which the clinician brings to bear on his cases. Our system of medical training recognizes this fact in requiring that the student be given every opportunity in the laboratory to develop the critical way of contemplating things that must be employed when interrogating Nature.

It is not merely a coincidence that the periods of most rapid medical progress (Hippocratic, Alexandrian, Galenic and modern) have also been the periods of greatest activity in the pursuit of animal experimentation or its equivalent. Furthermore, it has not been merely a matter of chance that in each of these periods the most highly esteemed men (Hippocrates, Erasistratus, Galen, Harvey) were at one and the same time practitioners of medicine and animal experimenters, actually or in effect; and that at least two of them (Hippocrates and Galen) were the greatest clinicians of their times as well as the authorities of clinicians for centuries after them.

They were the authorities not alone in the particular fields in which they had conducted animal experiments, but, as a matter of fact, in every field of medicine. Is it not, therefore, permissible to assume that the relatively small number of experiments, for the performance of which they managed to snatch a few moments here and there from their clinical activities, gave to them the attitude of mind that made them the fountain-heads of all medical knowledge during the long periods of medical aridity that succeeded them?

In order, then, to give a just valuation to the debt which the physician of to-day owes to animal experimentation, account must be taken, not only of the results capable of more or less direct application to the practice of medicine, but also of such observations and experiments on man as are stimulated by experiments on animals and of the attitude of mind of the physician toward his patient determined by the scientific, and therefore critical, atmosphere surrounding his activities.

I. THE DISCOVERY OF THE CIRCULATION

The story of the discovery of the circulation of the blood has been so frequently told that it will not be necessary to review it here in any great detail. Indeed, my only reason for relating it at all is to attempt to show the part played by animal experimentation in its unfolding. The limited scope of this paper compels me to confine myself to the most important phases of, and contributions to, the subject.

The earliest recorded views on the physiology of the blood-vessel system that are entitled to serious consideration are those of Hippocrates. There seems to be no good reason for believing that Hippocrates actually performed carefully planned experiments on animals. The statement is, however, made[1] that Hippocrates (the name stands for a period rather than an individual) probably acquired his knowledge, among other ways, through observation of votive offerings, of slaughtered animals, and of injuries received in war and peace. These are tantamount to animal experiments; they are chance operations on living animals. Such slow and uncertain methods of acquiring knowledge must, however, have led to the development of a far from perfect theoretical scheme of the blood-vessel system. I call attention here only to his observation of pulsation in the aorta and pulmonary artery with the obvious comment that this phenomenon could have been revealed only by viewing the artery exposed in the living animal.

Whether Aristotle performed experiments on animals seems to be a matter of dispute.[2] In any event, however, his views are probably mainly the outcome of reflection based on dissection and the accumulated knowledge of his time. And in many respects, it might be added, Hippocrates was nearer to the truth than Aristotle.

The contribution of Praxagoras to the physiology of the blood-vessel organs consisted in drawing more clearly than had Hippocrates the distinction between the arteries and veins, and in showing that "the phenomenon of pulsation, previously regarded as a common attribute of arteries and veins, really belonged only to the arteries. . . . They were, furthermore, distinguished by the nature of their contents; for, while the veins were still considered as receptacles for blood, the arteries, according to the new view, contained no blood, nor any liquid material, but only an invisible gas or air."[3]

I have not succeeded in discovering the source of Praxagoras' views on the pulse; it is, however, evident that they could have arisen only from experiments or chance observation on living man or animals. His erroneous conclusions that arteries contained air must have

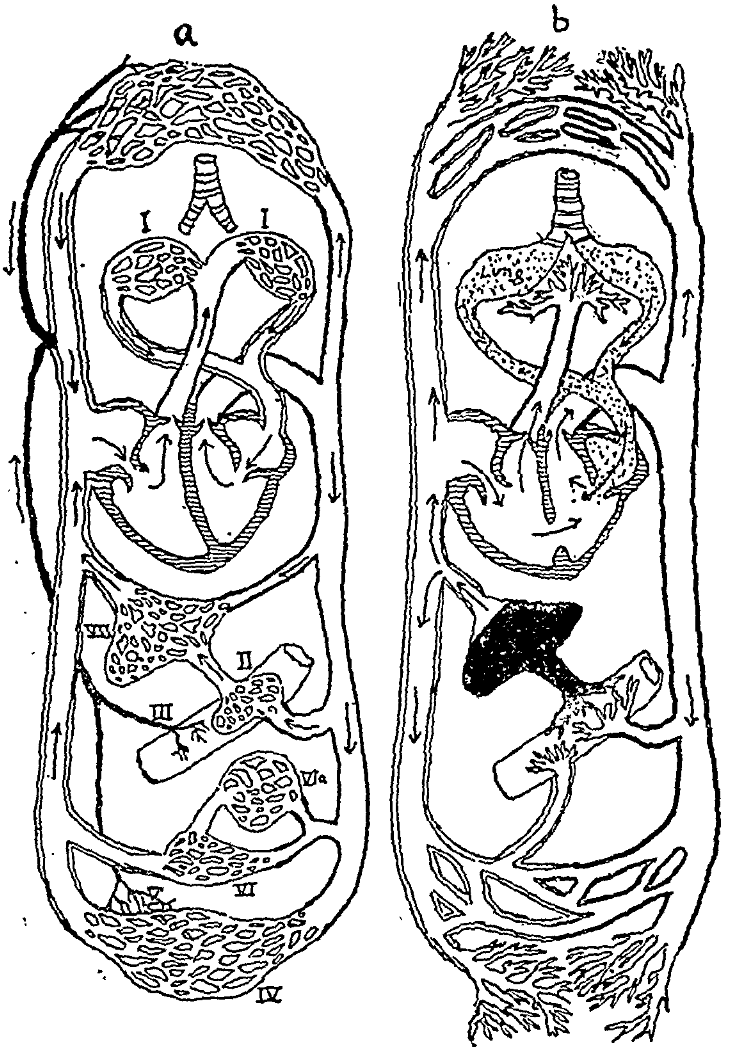
3. Dalton: History of the Circulation, p. 38.

been drawn from observations on dead, not on living animals.

The next important contributions to the physiology of the blood-vessel organs seem to have been made by Erasistratus. They were based on experiments on animals[4] and on dissection of the human body. He seems to have been unduly influenced by the views of Praxagoras: the veins still contain nourishing blood, the arteries "vital spirits." Experimentation, however, forced him to proceed one step in advance of the views then held and admit the existence of "synanastomoses" of the arteries and veins, which, however, allowed blood to pass into the arteries only under abnormal circumstances, as in plethora and when an artery is opened.



Scheme of the circulation (Nicolai); (a) according to Harvey (modified); (b) according to Galen (reconstructed). Heart-wall shaded; arteries heavily contoured; veins doubly contoured; capillaries lightly contoured; lymphatics (nutriment) solid black; air dotted; I, lung capillaries; II, intestinal capillaries; III, chyle capillaries; IV, somatic capillaries; V, lymph spaces; VI, renal capillaries; VIa, glomerular capillaries; VII, liver capillaries.

Erasistratus also describes accurately "all of the cardiac valves and their action. According to him, they provide the mechanism by which the heart alternately takes in and expels blood on the right side and pneuma on the left."[5]

There now occurs a gap of almost 500 years in the progress of medical science and art, and there seems to be no evidence that careful animal experiments were made during this interval. The gap is closed by the activities of practically a single individual, Galen, through whose animal experiments, coupled with keen clinical observation, the physiology of the blood-vessel system was advanced another step.

Galen's main contribution to this subject consists of the proof that the arteries contain blood and not pneuma. Two experiments are offered as proof of this fact:

1. "Expose an artery of a living animal. Then open it by applying to it, as you choose, either the point of a writing style, a needle, a slender scalpel, or any similar instrument that will make a narrow cut. Blood will at once exude. The artery, then, must have contained blood and not pneuma.

2. "The artery of a living animal is exposed by dissection, and, after isolating it with a cord on two sides and then opening it in the middle, we showed it to be full of blood."[6]

Galen's conception of the blood-vessel system is very well illustrated in the accompanying diagram (b). The nutriment taken up from the alimentary canal is converted into blood in the liver. Thence it is conveyed by the veins to all parts of the body, including the lungs (through the pulmonary artery), for the purpose of nourishing them. "The venous blood was dark, thick, and rich in the grosser elements of nutritive material." From the air carried through the pulmonary vein to the left ventricle from the lungs the vital spirits were extracted and added to the blood.[7] Or, according to another account,[8] the blood, traveling back and forth in the pulmonary vein, transported the pneuma from the lungs to the left ventricle. "The arterial blood (then) was thinner, warmer, bright-colored and, above all, spirituous." "As every organ is supplied with both arteries and veins, it can absorb each kind of nutriment in due proportion for its own needs." "The pulse was due to a 'pulsatile force' resident in the walls of the artery, but derived by them from the heart, in which it also existed. This was a force of active expansion, dilating the artery and attracting fluids into its cavity; while its subsequent contraction caused an expulsion of its contents in the same degree. Thus the diastole of the artery was an active, and its systole a passive movement."[9]

These views of the blood-vessel system prevailed until the Renaissance. At this time the dissection of the human body, which previously had been forbidden, led anatomists first to question some of the Galenic physiologic doctrines and then to seek the answers in the living animal. Thus was animal experimentation revived after a 1,200 years' sleep which began with Galen's death.

Vesalius, the father of anatomy, showed experimentally that the pulse was not dependent on the uninterrupted connection of the walls of the arteries with the heart, as Galen had maintained, since the peripheral part of a severed artery, connected with the heart by means of a cannula, still continued to beat.[10]

The next step was the refutation of the view handed down from the earliest times that the blood passed through the ventricular septum from the right to the left side, and the substitution in its place of the idea of the lesser circulation. Servetus, religious reformer and physician, was the first to surmise this course of the blood from the right to the left ventricle. In a book entitled "Christianismi Restitutio," dealing almost exclusively with questions of religion, there is inserted a strikingly clear description of the pulmonary circulation. No mention is made of animal experiments, and it is usually stated[11] that Servetus jumped to the conclusion which Realdus Columbus subsequently proved by means of experiments on animals and probably in complete ignorance of the views of Servetus on the subject.[12] It should not be forgotten, however, that Servetus' argument was based on the then known physiology of the circulation, which was the result of animal experimentation. In his experiments Columbus "always found the arteria venalis (pulmonary vein) containing no air, but full of arterial blood and yet not pulsating.[13] Columbus, it might be added, was thoroughly imbued with the importance of animal experiments in the elucidation of the functions of the blood-vessel system. "One learns more in a day from the vivisection of a dog," he says, "than from feeling the pulse or from reading Galen for months."[14]

There seems to be some difference of opinion as to whether Cæsalpinus is to be credited with making any contribution of real value to our knowledge of the blood-vessel system. Whereas, Dalton,[15] on the one hand, maintains that the main purpose of Cæsalpinus was "to defend the physiologic ideas of Aristotle as against Galen, rather than to carry the doctrine of either to a further development,"[16] Foster and the Italian authors,[17] on the other, concede to Cæsalpinus the recognition not alone of the true action of the heart-valves and the pulmonary circulation, but also of the fact that "the flow of blood to the tissues took place by the arteries and by the arteries alone, and that the return of the blood from the tissues took place by the veins and not by the arteries." And, whereas, Boruttau[18] states that Cæsalpinus did not clearly understand the greater circulation—the transit of the blood from the arteries to the right heart through the veins—Luciani quotes the following experiment as showing that Cæsalpinus had thoroughly mastered the conception of the circulation of the blood: "He [Cæsalpinus] observed that if in a living animal a vein be exposed, tied and shortly thereafter cut into on the capillary side of the ligature, the first blood to exude is of a dark color, while that coming later is lighter. This observation led him to assume the existence of anastomoses between the arteries and the veins."[19]

In view of the difference of opinion in regard to the value of the contributions of Cæsalpinus, we may be justified in concluding that, whatever his views may have been, they could not have been clearly and consistently stated. Possibly it was for this very reason that the doctrines of Cæsalpinus made no impression on his contemporaries. It would appear that little heed "was paid to them until they were disinterred, so to speak, by antiquarian research."[16]

How different the reception accorded Harvey's tract, "On the Motion of the Heart and Blood in Animals!" Whereas no notice had been taken of the views of Cæsalpinus in fifty-seven years, i. e., up to and after the time Harvey had committed himself in print, before sixteen years had elapsed Harvey's views had been subjected to published criticism, both favorable and unfavorable. The unfavorable criticism, it should be added, came, not from experimenters, but mainly, if not exclusively, from clinicians who, through fear that the new doctrine would wreck completely the fabric of medicine as then practiced, unwisely considered it better to bolster up the tottering structure with the old views than to rebuild it on the firmer foundation of animal experimentation. Those who then and since have put Harvey's views to the test of experiment have succeeded in substantiating him in all but a few minor details. The reason for the stability of Harvey's views may be gleaned from the well-known introductory words to the tract which laid the foundation of modern experimental medicine:

> When I first gave my mind to vivisections, as a means of discovering the motions and uses of the heart, and sought to discover these from actual inspection, and not from the writings of others, I found the task so truly arduous, so full of difficulties, that I was almost tempted to think with Fracastorius, that the motion of the heart was only to be comprehended by God. . . . At length, and by using greater and daily diligence and investigation, making frequent inspection of many and various animals, and collating numerous observations, I thought that I had attained to the truth, that I should extricate myself and escape from this labyrinth, and that I had discovered what I so much desired, both the motion and the use of the heart and arteries. From that time I have not hesitated to expose my views on these subjects.[20]

With the appearance of Harvey's work, the blood-vessel system, with at best imperfectly understood functions, becomes known to the world as the circulatory system, a term that stands at one and the same time for a system of organs and the mechanism thereof.

Harvey's demonstration of the circulation of the blood was incomplete; he had to assume the existence of "porosities of the flesh" in order to account for the passage of the blood from the arteries to the veins. Four years after Harvey's death, however (1661), the missing link was supplied by Malpighi, at one and the same time physician, anatomist, physiologist, histologist and the founder of scientific pathology. With the aid of the microscope, Malpighi succeeded in following in the lung of the living frog the course of the blood from the arteries through the capillaries into the veins, "so that," to use Malpighi's words, "the circulation of the blood is evidently exhibited."[21]

Thus, in barest outline, was the fundamental action of the blood-vascular system determined. The necessary facts, it has been seen, were gathered from all sources; the most important and decisive ones, however, were all the outcome of experiments on animals. Inferences from structure were made by all investigators; but, unsupported by experiment, they failed, even in the hands of Harvey, to lead to the truth. Nor could the case have been otherwise; a new mechanism, to be understood, must be seen and studied while in action.

The discovery and demonstration of the circulation of the blood ends the first phase of the physiology of the blood-vascular system and begins the second. With this second phase the physiologists of to-day are still concerned; it has to do with the elaboration of the details of the circulation. The limits of this paper make it impossible even to enumerate the lines along which the investigations have been carried, were the list to include only those of direct practical significance, and those in which animal experimentation has played a part. For the purpose of recalling to the mind of the reader some of the more important results of this activity, mention may, however, be made of the discovery of the automatic action of the heart, its regulation through the inhibitory and acceleratory nerves, of the vasomotor

March 18. Private practice. Dr. So	21		Wine-red fluid	0	Negative. —
Private practice. Dr. W	22	Dark red (little)	Red fluid	20	Very weak. ?

It has been the custom to call the reaction "negative" or "positive," and if positive, "very weak," "weak," "medium," "strong," or "very strong." Such terminology, by its own nature, makes for inexactitude, which is anything but desirable, to say nothing of being unscientific. The human mind cannot grapple with adjectives. It needs figures. Completely to grasp variations of a color-scheme or quantitative gradations, we must obtain our impressions numerically. The terms are from zero to one hundred. No one would think of writing a hemoglobin estimate as pale pink, pink, red, dark-red, crimson, etc. We have determined what intensity of color in hemoglobin represents 100 per cent., and we have readjusted our conception of weaker concentrations accordingly. A similar, if not homologous, method would be of great use in writing the Wassermann reaction, and it is such a method which I am about to present.

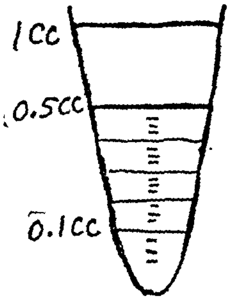
The Wassermann test is based on a few simple facts. Antigen produced from syphilitic liver, guinea-pig's heart or beef-heart, according to their respective availability, in solution of a given determined strength; a 20 per cent. solution of inactivated serum of the patient to be tested; and a 10 per cent. solution of complement from the uninactivated serum of a guinea-pig, each solution being in the bulk of 1 c.c., are poured together in a test-tube and remain in a thermostat or water-bath for one hour at body temperature. If the suspected serum contains suitable amboceptor the antigen and complement will be linked, and the reaction will be one which we consider positive. We must in some way determine whether such a process has occurred. This we do by introducing 1 c.c. of washed sheep's erythrocytes in a 5 per cent. suspension, and 1 c.c. of a solution of rabbit serum of known hemolytic titer, the rabbit having been immunized to the aforesaid red corpuscles. After the addition of these two ingredients the liquid in the test-tube is pink in color and opaque. The tube is once more subjected to body temperature for one hour and the result is noted. If the complement be not bound to the antigen by the human amboceptor, it will be free to link itself with the hemolytic system and hemolysis will take place.

The crux of the entire reaction is to determine what becomes of the complement. If it join the system composed of antigen and human amboceptor, the reaction is positive; if it join the system consisting of sheep's red blood cells and sheep's amboceptor, the resulting blood laking denotes a negative reaction. Between the two extremes of total binding of the complement and total hemolysis, the gradations are infinite. The proportion of bound and free complement varies, so that visual signs of binding or laking are expressed in terms of opacity, translucency, or transparency of the fluid at the end of the test. These variations have been recorded graphically by the minus sign for a negative reaction, the plus sign for a positive, and two plus signs for a strongly positive. Almost everyone has his own system. Obviously such a method would not only vary between two individuals, so that the man who makes the test might have a different idea of the value of his hieroglyphics from that which would be connoted to anyone else, but it would vary from day to day as to the investigator himself. Thus we have had, and have, no unit of measure to standardize results. This want can be met by a method which is simplicity itself.

---

[22] It will be quite impossible to give full credit to all investigators in the fields referred to. Nor am I sanguine enough to believe that I have succeeded in my attempt to mention the first workers who have called the attention of the scientific and medical world to the subjects to be discussed.

Into each test-tube we have introduced, as has already been stated, 1 c.c. of a 5 per cent. suspension of sheep's erythrocytes. In volume this is 1/20 c.c. In the course of the test either the entire volume is hemolyzed, or none; or only a variable portion. All we need do to determine this portion is to see what fraction of 1/20 a cubic centimeter remains at the termination of the test. After from sixteen to twenty-four hours all surviving red blood cells have descended in the tubes, and according to their number the deposit is heavy or light. They lie unevenly, however, in the concave bottom of the test-tube, and thus the eye can distinguish only the greatest quantitative differences in the red cells. In a pointed centrifuge tube these difficulties are somewhat less, and the gradations in the deposit easier to determine, but in different tubes of varying calibration inaccuracies are inevitable. Therefore, working on this principle, I employed graduated centrifuge tubes and centrifuged the contents of my test-tubes sixteen hours after removal from the thermostat. In this way I was able to read off the number of surviving red blood cells. I count total hemolysis as zero, and 1/20 c.c. of erythrocytes in bulk, or the maximum amount, as one hundred. By comparing the volume of surviving erythrocytes according to this scale, and recording the result in per cent., one immediately has a quantitative idea of the reaction. Thus, if 1/40 c.c. of red blood cells are left, the reaction is 50 per cent.; if 1/30 c.c., 66⅔ per cent. If n equals the reading in the tube, and x the desired percentage, the equation is:



Graduated centrifuge tube.

$$1/20 : 1/n = 100 : x$$
$$x/20 = 100/n$$
$$nx = 2000$$
$$x = 2000/n$$

The bottom of the average graduated centrifuge tube is divided off as in the diagram, each fine space representing 1/40 c.c.

In this tube the graduation is too coarse. I shall have tubes made with thicker walls, finer calibration and larger spaces, and shall subsequently render a new report with my more accurate apparatus. This one is to be regarded as a preliminary communication, but it will be serviceable to indicate the value of the method.

Among about 400 Wassermann reactions I have made both here and abroad, I have as has already been stated, always been struck with the difficulty of imparting a conception to a second person of the strength of the reaction. The accompanying table will show at once the advantage of the new method over the old. But let me for a moment describe what is seen in a test-tube in which the reaction has been made after sixteen to twenty-four hours have elapsed. With a negative reaction we have merely a clear wine-red fluid; in a strongly positive test the red cells lie heaped at the bottom and above them the fluid is pure white. If the test be positive, but weaker, the cells are below and the supernatant fluid, containing dissolved hemoglobin, is pink, salmon-colored, deeper red, etc., according to the amount of hemoglobin in solution. The stronger the reaction the greater are the number of corpuscles at the bottom and the paler the color of the fluid. The weaker the reaction, the deeper the intensity of the fluid and the smaller the number of corpuscles. These differences expressed mathematically become definite and objective instead of subjective and vague, as they have been heretofore.

To procure the results in the accompanying table I did the reaction as outlined, and after sixteen hours shook up the contents of each tube, centrifuged for two or three minutes by electricity, and noted what part of 1/20 c.c. of corpuscles remained, calculating the percentage by the formula already mentioned. The character of the supernatant fluid after centrifuging corresponded exactly with that in the tube, as described in the table, before centrifuging. I shall apply this method to the Noguchi modification and publish my results of this together with further observations on the original test. The histories of the cases cited here have no bearing on the theme. Thus they were omitted in order to hasten my paper toward its object and its conclusion. In the table I represent side by side the old method and the new, for a contrast of the obvious inaccuracies of the former with the definiteness of the latter will speak more forcibly than countless paragraphs.

AN AUSCULTATORY PHENOMENON MET IN INFANTS AND CHILDREN

H. LOWENBURG, A.M., M.D.
Instructor in Diseases of Children, Jefferson Medical College; Pediatrist to the Lebanon Hospital, and to the Jewish Maternity Hospital; Pediatrist to the Jewish Seaside Home, Ventnor, N. J.
PHILADELPHIA

The sign to which I wish to direct attention, so far as I am aware, has not been described previously. My search of the literature has been confined to the standard works on diseases of children. Briefly it may be stated as follows; normally the inspiratory murmur over the left side, especially posteriorly, in infants and children is decidedly louder and harsher than over the right side; or, reversely, the inspiratory murmur over the right side is weaker and less harsh than over the left side. Why this is so I can not explain positively, but I suspect that it may be due, in part at least, to the fact that in the left lung there being but two lobes, the same amount of air as enters the right lung is not distributed over as great an area as it is in the latter. Whatever its physics or its etiology may be I no longer have any doubt that this sign does exist as a normal phenomenon of the child's chest and that it has an important bearing on the diagnostics of pulmonary conditions. It has been regularly sought and found by myself and my assistants in all normal children, at my clinic at the Lebanon Hospital, Philadelphia, for the past year. Dr. Charles Mazer, whose attention I first directed toward it more than a year ago, informs me that since then he has examined every child that has passed under his care for it, and that he has never failed to find it in all normal children. That a recognition of this sign or the relative difference between the loudness and harshness of the inspiratory murmur of the two sides of the child's chest is of great aid in permitting a correct interpretation of pathologic conditions affecting the lungs and pleura can be best illustrated by the brief citation of a few cases.

Case 1.—Female infant, aged 16 months. Normal birth, breast-fed, dentition normal; has ten teeth now; wasted and marantic in appearance; came to my clinic at the Lebanon Hospital with the diagnosis of marasmus; had been treated for this in another hospital for three weeks without benefit; no vomiting and bowels normal. The child's age, the presence of ten teeth and the absence of digestive symptoms precluded any gastro-intestinal condition as a cause of wasting and made the diagnosis of true marasmus very improbable. The temperature by rectum was 99 F. Percussion gave but the slightest possible impairment of resonance on the left side posteriorly, extending with even less emphasis into the axilla. Auscultation showed that the breath sounds on the left side equaled in intensity and harshness those on the right. Because we had become accustomed to regard the sounds on the left as normally louder and harsher this equalization was looked on as a distinct and marked impairment of the sounds on the left side, but in a comparative sense only, and a diagnosis of fluid on this side was made. Exploratory puncture revealed pus, and after thoracotomy and drainage the child made a perfect recovery in about three months.

Case 2.—Female infant, 6 months old, seen in consultation. Diagnosis of bronchopneumonia of right side posteriorly had been made by the attending physician. He emphasized the impaired resonance under the angle of right scapula and pointed to some increase in the loudness and harshness of the breath sounds over this area. The child's temperature had been normal for ten days and leucocytosis was absent, but the child still coughed and had failed to gain, in fact, was considerably wasted. A careful examination of left side revealed slight impairment of resonance with breath sounds distinctly present but weaker than over the right side. There were no râles over the right side. The impaired resonance under the right scapula was regarded as due to the liver and the harsher than normal breath sound to an over-working lung, and the diagnosis of fluid on the left side was suggested. Puncture revealed a dirty-appearing, foul-smelling pus.

Case 3.—Male infant, 13 months old. Temperature 103 F., pulse 140, respiration 64; face flushed; alæ nasi moving. Physical examination showed the left side resonant and a few râles; breath sounds harsh and loud posteriorly on the left. On the right side was detected an area of impaired resonance extending from the lower half of the right border of the scapula latterally toward the right as far as the midaxillary line. The inspiratory breath sound was harsh and loud posteriorly equalling that of the left side; expiratory sound was slightly prolonged and blowing. Fine moist râles were also heard. The diagnosis was acute lobar pneumonia of right middle lobe. Crisis on the fifth day. On the seventh day the temperature rose to 103 F. Physical examination showed flatness on the right side posteriorly and distant râles with breath sounds weaker than on the left, but sufficiently audible to resemble in intensity and quality the normal sounds on the right side. In view of the previous history of pneumonia, the flatness and the displacement of the liver and the heart, the diagnosis of effusion was made and confirmed by puncture.

Case 4.—Male infant, 8 months old. Diagnosis of pneumonia on the left side was made by the attending physician. There was a cough, temperature of 102 F., pulse 110, and respiration 20; a few large moist râles were heard on both sides; chest was resonant throughout. The inspiratory sound was distinctly harsher and louder over left side posteriorly. I suggested that this was normal and made a diagnosis of simple bronchitis. Recovery occurred within three days.

Case 5.—A female infant, 17 months old, the daughter of a physician, had a temperature varying between 102 and 104 F. for the previous five days. The father feared typhoid fever, but one of his colleagues had made a diagnosis of pneumonia on the left side, noting the loudness and marked harshness of the sounds on this side when compared with the right. The suggestion was made that this was a normal phenomenon. Further physical examination of the chest was negative. The child apparently was in no pain. The right drum-head was found to be red and bulging. Diagnosis, acute otitis media. I suggested an aurist. Puncture of the ear-drum was followed by a free discharge of pus, and recovery.

Cases 1 and 2 illustrate the value of recognizing the fact that there is something wrong (usually presence of fluid) when the inspiratory sound on the left side loses in strength and equals or is less in intensity and harshness than on the right.

Case 3 shows that, with other features (impaired resonance, râles and prolonged expiration) present, when the inspiratory sound on the right side is harsh and loud, approaching that which is regarded as normal for the left, trouble, usually consolidation, exists in the right lung. The second part of the case illustrates that weak breath sounds on the right may lead to confusion and prevent a correct conclusion, as they are normally weaker on this side. In such instances we can only compare the character of the sounds with that which experience has taught us to regard as normal for this side. Therefore ausculation, unless the breath sounds are entirely absent, is of little value in diagnosing fluid on the right side. Dependence must be had largely on the history of the case, percussion and the displacement of internal organs.

Cases 4 and 5 illustrate that, unless one is familiar with this sign as a normal phenomenon, one is liable to regard it as indicative of a pathologic condition, especially pneumonia, on the left side. Case 5 further illustrates the importance of making a complete physical examination in every case of obscure fever, not neglecting the ear, even in the absence of pain.

CONCLUSIONS

1. Normally in infants and children there exists a marked relative difference in the intensity and harshness of the inspiratory sound of the two sides of the chest, that on the left being louder and harsher. This difference is best noted posteriorly.
2. The absence of this sign on the left usually means fluid in the left pleural sac.
3. The diagnosis of fluid on the right is made more difficult by reason of this sign.
4. The diagnosis of consolidation on the left is made more difficult.
5. Unless this sign is taken into consideration the diagnosis of pneumonia on the left is apt to be made when other conditions are responsible for the fever.
6. Consolidation should be suspected on the right when the sound on this side equals in harshness and intensity that which is normal for the left.
7. Equalization of the sounds on the two sides, that on the left being weaker than normal, usually indicates fluid on the left.

1502 Diamond Street.

Prophylaxis of Typhoid Fever.—The discussion on this subject which was carried through eleven meetings of the French Academy of Medicine was concluded by adoption of a series of resolutions advocating specific sanitary and hygienic measures. A resolution was voted down which stated that the danger of contagion from healthy typhoid bacillus carriers is negligible in comparison with the danger from contaminated water. The possible peril from bacillus carriers, sick or well, and the necessity for seeking them out were emphasized in the resolutions adopted.

MYIASIS

A REPORT OF THREE CASES OF PRIMARY RECTAL INFECTION[*]

J. L. NICHOLSON, M.D.
RICHLANDS, N. C.

It has long been known that man is one of those organisms in which myriads of parasites and pseudoparasites find conditions congenial to their growth, development and continued existence. Among these are the diptera, which form the subject of this paper.

The diptera include all the different varieties of *Brachycera* or flies from which the larvæ of myiasis originate.

The following facts may be noted in regard to flies as set forth in an interesting paper by McCampbell and Corper:[1]

> Some lay no eggs, living larvæ issuing from the female (viviparous). It has also been noted that when certain of the dipteræ become parasitic, no wings are developed. Nothing seems to be known as to whether the larvæ may reproduce, as has been noted in the embryonic types of some other forms of animal life. The sexual organs in the larvæ, according to most entomologists, are not completely developed until after the adult fly stage is reached. The larva is entirely different from the adult fly; and, during the pupal stage which intervenes all the organs of the larva, except the reproductive, undergo degeneration, and are regenerated. Such an arrangement suggests a very high specialization of these organs; and it may be possible that when these larvæ become parasitic within the body, reproduction may take place. It seems positive that the eggs can hatch and the larvæ grow to full size in the intestines of man. It has also been observed that larvæ may exist for long periods of time within the body.

Myiasis is the term applied to the accidental infection of the body cavities and of the skin by the larvæ of these dipterous insects.

This infection by fly larvæ was designated by Hope as myiasis; and the condition has since been divided by other writers into myiasis externa, or dermatosa, and myiasis interna or intestinalis.

The following are some of the leading or principal families of flies the larvæ of which produce this condition: (a) The "blue-bottle," flesh fly; (b) *Lucilia macellaria,* the screw-worm fly and (c) the *Dermatobia hominis,* a tropical American fly. These are chiefly responsible for the external varieties of the disease.

Among the flies producing myiasis intestinalis we find the common house fly (*Musca domestica*), the *Sarcophagia* or flesh fly and the *Anthomyia canicularis.*

The common house fly seems to be the source of infection in the three cases coming under my observation. The number of generations of this fly varies greatly with climatic conditions, supply of food and other factors. The number in North Carolina, according to Metcalf, would undoubtedly be from 10 to 14 broods a year. This fly, like many other insects, passes through 4 distinct stages in the process of development—the egg, the larva, the pupa, and the adult, the full process requiring from 10 to 14 days. The adult fly lays the eggs in suitable places, usually in stable manure, occasionally on human excreta and decomposing vegetable matter. The duration of the egg stage in favorable weather is but a few hours. The larvæ are white-pointed maggots from 1 to 2 c.m. in length, and composed of 9 or 10 well-defined segments. The larval or maggot stage covers a period of about five days in summer, varying greatly, however, with the weather conditions in general. The pupal stage may not extend beyond 5 days, while under other conditions, as in winter, it may persist for months.

It is universally held that the invasion of such body cavities as the ears and nose, and of the wounds on the surface, is the result of the accidental deposit of eggs at the point infected; and that those which are found in the intestines are ingested with the food on which the adult fly has deposited its eggs. It is evident that little if anything has been said of infection by rectum. Finlayson's suggestion of the possibility of such an avenue of infection stands out alone against the generally accepted teaching of infection by the mouth following the accidental swallowing of the eggs and newly hatched larvæ with food.

The history of the three cases which have come under my observation in the last three years, and which I now propose briefly to relate, points almost unmistakably to rectal infection.

Case 1.—*History.*—A native of Onslow county, North Carolina, married and mother of four children, ever since her first pregnancy, twenty years ago, has been suffering with "piles;" even prior to that time she suffered from painful menstruation and chronic constipation. For the last eight years her life has been still further burdened with rectal prolapse, proctitis and mucomembranous colitis. During this time her life has been that of a well-nigh bedridden invalid. She was absolutely confined to her room; a common stool chair with an opening in the bottom and "chamber" underneath, exposed to the flies, served her as a commode. In the summer of 1906 she discovered large numbers of small, white worms or maggots, as she calls them, in her stools, to which she called my attention. On examination, these organisms proved to be larvæ of the common house fly. During this summer as well as in 1907 and 1908, she had several recurrent attacks of the infection, each being manifested by expulsion of from fifty to several hundred dipterous larvæ. Preceding and accompanying each attack, digestive disorders, vomiting, colicky pains, abdominal distention and increased mucous bowel discharges—symptoms common to her—were greatly aggravated. At times these parasites were expelled massed or clumped in small balls, approximately the size of an ordinary marble; at other times they were equally mixed with liquid mucoid stools. After each expulsion there came a distinct amelioration of all the bowel symptoms. This patient, of course, was anemic, pale, almost cadaveric, suffering greatly with indigestion and all manner of abdominal and rectal distress.

Management and Course.—Having failed to prevent the recurrence of these attacks of myiasis by any manner of medication or rectal irrigation, and also failing to get her consent for proper operation, about the middle of the summer of 1908, I advised absolute protection of the anus from all approach of flies during the act of defecation. The result was a complete cure of the infection, without any subsequent recurrence to date, together with a marked improvement of the rectal and colonic troubles. Such satisfactory results, coupled as well with the statements of the patient that she had experienced no less than twenty such attacks during the summers of 1906-7 and 8, furnish the strongest and most convincing proof that this patient, at least, became infected by the deposition of the eggs of the house fly on the prolapsed rectal membrane during the time spent at stool on an open chair.

Case 2.—*History.*—A white man, aged 24, a merchant by occupation, first came to me for treatment in July, 1908. He was thin, decidedly feeble and anemic. Eight years prior to my interview with him he began suffering with slight rectal prolapse, which now was quite an inch with each bowel passage. For the past six years he had discovered at various times hosts of small white worms in his feces. He brought samples of these parasites for my inspection. These, which varied sharply in length and size, were the larvæ of the common house fly. He claims to have had dozens of these attacks during these five years; and stated that as many as 500 of these little worms were sometimes expelled at a single defecation, while at other times only a few or so accompanied each stool. In addition to symptoms previously mentioned, each of his attacks was preceded for 48 hours by sinking, depressed feelings, accompanied by burning, internal, colicky pains near the region of the umbilicus. These symptoms, to him significant of the approaching expulsion of maggots, loss of appetite, nausea, colic, and diarrheic actions, ushered in the attack. The first loose stool contained the majority of the larvæ, all being expelled in 3 or 4 stools. After this the diarrhea, burning colic, nausea and depression subsided. His life habit had been to be slow at stool and always to defecate in the horse stable, if possible.

---

[*] Read before Seaboard Medical Association (Virginia and North Carolina) at Norfolk, Va., Dec. 9, 1909.

[1] McCampbell, E. F., and Corper, H. J.: Myiasis Intestinalis Due to Infection with Three Species of Depterous Larvæ. The Journal A. M. A., Oct. 9, 1909, p. 1160.

Management and Course.—My injunction to him to quit the use of the horse stable as a privy and to use a closed vessel, caused a cessation of his infections from July, 1908, until August, 1909, when he reported the return of the maggot and pleaded guilty to a return to his horse stable practice. Another point of interest is that all the attacks of this patient came in the summer months, the earliest recalled occurring in April.

Case 3.—*History.*—The patient, a white woman, aged 50, married 30 years, and the mother of 9 children, in July, 1908, came to my office for treatment; she was pale, almost yellow in complexion, very nervous, and suffering with acute indigestion and diarrhea. The attacks, alternating with constipation, had troubled her at irregular intervals for 2 years or more. She came much distressed because she discovered that morning while at stool that hundreds of little white maggots had come from her bowel. This patient was a constant user of an open privy, and was a sufferer from internal piles, which at times came down during defecation.

Management.—The same advice to keep off the flies was given to this patient, but as I have lost sight of her, I cannot speak with positiveness of her recovery.

SUMMARY

Having thus cited the peculiarities of each of these cases, let me briefly submit the following summary as a closing feature, believing that the similarity of symptoms and surrounding conditions common to all three cases are of significant interest:

1. All the individuals affected were white adults, intelligent, fairly cleanly of habit and truthful of statement.
2. All suffered constantly or periodically with protrusion of folds of the rectum during defecation.
3. All were equally exposed to fly contamination during the process of defecation.
4. All suffered with more or less tenesmus, and were slow at stool, thereby offering ample opportunity for the deposition of eggs on the protruded membrane, smeared with feces, mucus and more or less blood.
5. All symptoms characteristic of these attacks ceased or were much improved with the expulsion of the maggots.
6. No recurrence of the infection took place in either of the first two patients so long as they followed my advice to protect the anus thoroughly from the approach of flies during the act of defecation. The third patient having been lost sight of, I am not able to speak with certainty regarding recurrence.

Finally, the facts set forth in these cases seem to me to demonstrate, beyond a reasonable doubt, that the avenue of infection was by rectum. This opens up an interesting field for further observation, and suggests that a large number of cases of myiasis intestinalis occur in persons affected with anal and rectal disease, and that in them it is due to the fact that the proper precaution to prevent rectal invasion has not been observed. The remedy, from this point of view, is evident.

Electrotherapy.—Electrotherapy must not be regarded as a cure-all, nor as a placebo, but if used in connection with other therapeutic measures it will be found to be a very useful servant.—H. M. Imboden, in *Albany Medical Annals.*

EXTRAUTERINE PREGNANCY

DISCHARGE OF FETUS BY RECTUM; PELVIC ABSCESS; INTESTINOVAGINAL FISTULA; GENERAL ADHESIVE PERITONITIS; PHLEBITIS OF BOTH LEGS; RECOVERY

J. R. LAUGHLIN, M.D.
HAGERSTOWN, MD.

Patient.—Mrs. J. B., aged 24; married six years; no children.

Present Illness.—She had missed two periods and was suddenly seized with severe pain and cramps in right side, followed by a bloody discharge which had continued three weeks, when I first saw her, June 8, 1908.

Examination.—The uterus was slightly enlarged and firmly fixed; there was a slight bloody discharge from the cervix. The pelvic organs were very tender and there was a board-like hardness over the hypogastrium. Temperature was 100 F., pulse 88.

Course of Disease.—The patient was treated for pelvic peritonitis for four weeks with improvement of symptoms, but no change in rigidity. July 5, her bowels became very loose with bloody stools, and on July 6 a partially decomposed fetus about two inches in length was passed at stool. A few days later the temperature rose to 104 F. and an incision made in the vaginal vault evacuated a profuse purulent discharge with fecal odor. Drainage was kept up for two weeks, but on investigation a recto-vaginal fistula was found by which feces were discharged through the vagina. Four weeks after the operation the fistula had closed, the vaginal discharge had ceased, and the woman seemed well when she suddenly developed a left femoral phlebitis; this promptly yielded to rest and elevation and she was discharged cured August 20.

Subsequent History.—Four months later she had what appeared to be a typical attack of acute appendicitis. An incision was made in the median line of the abdomen but the adhesions were so dense that the appendix could not be reached, as many as three loops of intestine were found firmly adherent together and it was impossible to find a piece of free intestine more than six inches in length. A few cysts filled with fluid were found; these were opened and an uneventful recovery followed. Four months later she had a similar attack, except that the pain was not especially localized.

She was put to bed and given local treatment, and improved for two weeks, when the old fistula reopened, but closed again in a few days. She again developed a phlebitis, this time in the right leg. By July 23, 1909, all symptoms had disappeared and she has continued well since.

146 West Franklin Street.

ACUTE PERFORATION OF A DUODENAL ULCER

J. T. ULLOM, M.D.
PHILADELPHIA

Patient.—S. M., aged 63, a married man. Aside from the case of a sister who died at 73 of "stomach trouble," the family history offered nothing of interest. The patient had had no serious illness beyond the ordinary diseases of childhood, and malaria at 38, but had suffered more or less for the last 20 years from stomach trouble, diagnosed by Dr. Osler near the beginning as "nervous dyspepsia."

Present Illness.—The patient was well during the winter of 1907-08, but in March, 1908, he had what he called an ordinary bilious attack, with clay-colored stools and vomiting of greenish material, after which he continually had more or less trouble which he referred to his stomach. This usually manifested itself two or three hours after dinner with distress, distention and belching; the attack, if not relieved by vomiting, would be followed by discomfort all night, accompanied by acid eructations. The vomitus was sometimes green, sometimes brown and often of amazing quantity. There was never any suggestion of blood in the vomitus nor was it ever coffee-ground in character. Gastric analyses made on numerous occasions showed a total acidity of about 40 and a free hydrochloric of about 20.

Urine analyses showed no abnormality except a specific gravity of 1010. Physical examinations made during this period showed nothing abnormal. The lungs and heart were normal, the abdomen contained no mass and there was no area of tenderness. The skin was sallow and the face expressive of illness. Despite his wretched condition and considerable loss of flesh the patient went to his office every day during the spring and early summer of 1908. About 11 o'clock one morning he had an attack of pain, referred to the right side of the abdomen, so severe as completely to prostrate him.

Examination.—The temperature was subnormal, the pulse 120, and very weak and the patient was bathed in a cold perspiration. The abdomen was extremely rigid, and exquisitely tender and the patient resisted any attempts to examine it.

Operation.—It was realized that some serious intra-abdominal accident had occurred; the patient was hurried to the Germantown Hospital, and a laparotomy was performed. A large incision was made, and a perforation was found in the duodenum just outside of the pylorus. This was closed and the abdominal wound sutured. The patient was returned to his room as quickly as possible, as his condition became very bad while on the table.

Post-operative History.—The patient reacted nicely and that evening at 6 was conscious, although uncomfortable. Temperature 98.6, pulse 96, respiration 20. At times during the afternoon his respirations were Cheyne-Stokes, but they were much better toward night. His condition remained pretty good for the next two days except for a complete suppression of urine. At the end of that time he passed a large quantity of urine and continued to void large quantities daily. This showed a trace of albumin and some hyaline and granular casts. Temperature and respirations remained satisfactory and the abdomen showed no signs of peritonitis. After seventy-two hours, on September 13, the patient became very restless, slightly delirious and hard to control, got out of bed, and tore out the stitches in the abdominal wound, allowing the wound to gap. He remained delirious and extremely restless. About midday, September 15, he was seized again with agonizing pain in the abdomen of apparently the same character as the initial pain, which could be relieved only by repeated injections of morphin. He died at 6:30 p. m. that day.

Post-mortem Examination.—A partial autopsy was obtained and there was found a duodenal ulcer just outside of the pylorus running longitudinally and a trifle obliquely, about 4 cm. in length, and 1.5 cm. in width. At the end of this ulcer nearest the pylorus was the perforation which had occurred on September 10 and which showed no signs of healing. At the other end of the ulcer was another perforation that had apparently taken place at 12 o'clock on the day of death, as manifested by the severe paroxysm of pain at that time. On microscopic examination there was complete erosion of the mucosa, submucosa, and the muscular layers and at the edge of the ulcer there was increased fibrous tissue and some round-celled infiltration. The kidneys were smaller than normal and the capsule stripped with some difficulty. On section the cortex was slightly contracted and microscopically the picture was that of chronic diffuse nephritis.

This case was of interest to me as offering considerable difficulty in diagnosis. Here was a man of 63, with a history of dyspepsia running back for twenty years, with periods of comfort alternating with periods of considerable gastric distress. After a year of good health, he began to lose flesh, became anemic, and experienced pain some time after meals, which was relieved by vomiting. There were acid eructations, but rarely spontaneous vomiting and no hematemesis, melena, or localized tenderness. The diagnosis now seems an easy one but before the perforation it was felt that there was very little on which to base a diagnosis. When the perforation occurred it was realized only that a rupture of some viscus had occurred, but whether appendix, stomach, intestine or gall-bladder could not be told with any degree of certainty.

When the literature on duodenal ulcer was examined, it was found that many cases are absolutely latent and perforation or a serious hemorrhage are the first indications of an ulcer. Gibbon and Stewart present seven cases of perforated duodenal ulcer and in three of these there was absolute latency, and in the other four, one showed symptoms of indigestion for twenty-four hours, one for a week, one for two weeks, and one for several months. Musser's case showed symptoms of hyperacidity for ten years. Smith found symptoms referable to duodenal ulceration in only three out of fourteen cases, although nine patients had digestive disturbances. Haggard states that ulcer of the duodenum very frequently exists without symptoms and a fatal hemorrhage or a perforation are the first signs of trouble. Morot, according to Haggard, finds that 20 per cent. of duodenal ulcers are latent. Shaw and Berry examined 157 cases post mortem and found that no history could be obtained in ninety-one. Moynihan states that many ulcers remain latent for a long period.

The classical symptoms of duodenal ulcer are three, pain, melena, and hematemesis. Pain is the most constant symptom found and usually comes on from one to three hours after meals. It is coincident with the discharge of the acid chyme into the duodenum and depends on the character of the food ingested. Sometimes it is relieved by eating. This is explained by the closure of the pylorus when food is introduced into the stomach. The pain is often relieved at its acme by vomiting and the patient immediately becomes normal again. The position of this pain is usually to the right of the median line and below the ribs in the position described as that of the gall-bladder.

It varies much in severity from a simple discomfort to a most agonizing pain and it rarely is found to radiate. Tenderness, which must be considered with pain, is not often found, owing, no doubt, to the position of the duodenum. The presence of blood in the stools, in the absence of hemorrhoids, is of course evidence of ulceration in the alimentary canal somewhere, and taken in connection with the characteristic pain, makes the diagnosis almost certain. Blood may appear in the stools as a frank hemorrhage, as old blood in tarry stools, or as occult blood. Every patient presenting symptoms referable to gastric or duodenal ulcer should be examined for occult blood. The vomiting of blood is more apt to occur in ulcer of the stomach, but is sometimes found in duodenal ulceration. In the twenty-three cases of Moynihan, hematemesis and melena occurred in four, hematemesis alone in three, and melena alone in two. No doubt in many cases blood would be found to be discharged by the bowel if more examinations for occult blood were made There are two grave accidents to be feared in duodenal ulceration, perforation and hemorrhage. Perforation gives the symptoms common to perforation of any abdominal viscus, prostation, weak rapid pulse, cold extremities, cold sweating, intense abdominal pain with board-like rigidity succeeded in a few hours by tympanites and the symptoms of peritonitis. The diagnosis can be made only on the history of the case and the location of the pain and tenderness. Hemorrhage is shown by pallor, shock and the appearance of blood at the anus. If a large blood-vessel is eroded death is apt to occur before anything can be done.

This case was a very instructive one and it seems now that a closer analysis of symptoms with an examination for occult blood would have made a diagnosis possible.

IMPROVED ETHER INHALER AND BLOOD ASPIRATOR

EDWIN PYNCHON, M.D.
CHICAGO

In my paper in The Journal, June 20, 1908, were illustrated and described an anesthesia apparatus and a blood aspirator, which were designed for use in surgical operations in the mouth and throat. Having since then improved these devices I will describe briefly the changes made therein, which are shown in the illustrations here given. In place of the foot bellows formerly employed in the anesthesia apparatus (Fig. 1), I have substituted the less expensive and simpler Politzer air-bag of the six-ounce size, provided with an inlet valve in the bag, and have supplied, in addition, a similar valve in the tube leading therefrom to the ether bottle, in order to prevent any rearward motion of the air while the hand bag is being expanded. In this way the air current supplied is intermitting, and its motion is timed with the patient's inspirations.

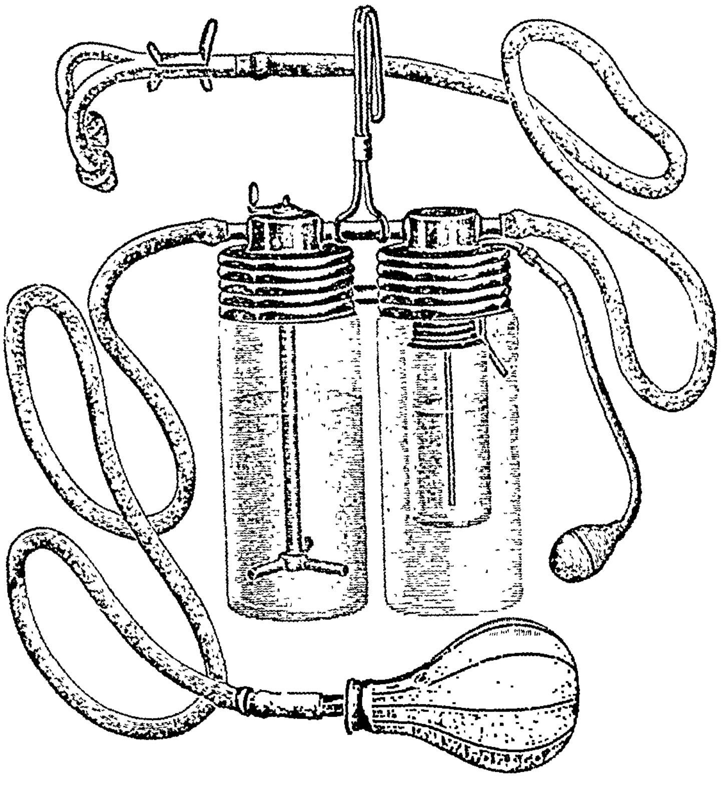

Fig. 1.—Anesthesia apparatus.

The bottles are of different shape, and of larger size, than those formerly employed. The first bottle is not more than two-thirds filled with ether. The second, or mixing bottle, as suggested by Brophy, prevents the passing to the patient of the fluid anesthetic, as might otherwise occur should the anesthetic bottle be too nearly filled, or should too much force be employed in the supply of air. The air-tube in the ether bottle is provided with a three-pointed extension, so as to divide up the entering air, and cause its better exposure to the ether. By operating the lever on the top of this bottle, which swings 180 degrees, the passing air current may be more or less forced to bubble through the ether.

In the second bottle, which was formerly employed as only a mixing or safety chamber, I have been enabled, owing to the wide mouth, to introduce a smaller bottle for the use of chloroform, which thus can be added to the etherized air current if at any time required. By slightly compressing the small connecting rubber ball the air above the chloroform is condensed, so as to force outward into the larger bottle a few drops thereof through the escape tube. At all other times the etherized air passes about this bottle without absorption of chloroform.

From the mixing bottle a rubber tube leads to the patient; it terminates in a Y-shaped tip, with conical hard rubber plugs, so as to fit tightly into the patient's anterior nares. In order to meet the requirements of different ages, from infancy to maturity, I have found that four sizes of these tips are required. The patient is first anesthetized with the mask, in the usual manner. Then a change is made to the inhaler as the operation is begun. In this way the anesthetist is at no time in the way of the operator, and an even anesthesia can be easily maintained. Furthermore, as all the etherized air is compelled to pass through the nose, it is both warmed and humidified before reaching the lungs.

In the blood aspirator the same size and style of bottle is employed as those used in the inhaler (Fig. 2). Being wide-mouthed it permits of easy emptying of the coagulated blood. The aspiration tip differs from the one formerly employed, and terminates in a cage of perforated metal, with one large conical opening at the end for blood clots. This cage can be unscrewed and removed for cleansing. With this device, after the mouth gag has been adjusted, blood and saliva can be removed, and the operative field kept fully exposed. The exhaust, when required, is created by the air pump, which is operated by a nurse. The receiving bottle is supported by a tape from the neck of the assistant who, while holding down the tongue with a depressor in his left hand, has in his right hand the aspiration tip for use when required. The patient is in the Rose position, whereby the larynx is above the plane of the pharynx. With the aid of the aspirator, accumulating fluids are removed, and are therefore not drawn in the lungs, causing respiratory arrest, or swallowed, causing vomiting. Through a combination of the improved anesthesia and the aspiration, postoperative complications are to a large extent avoided.

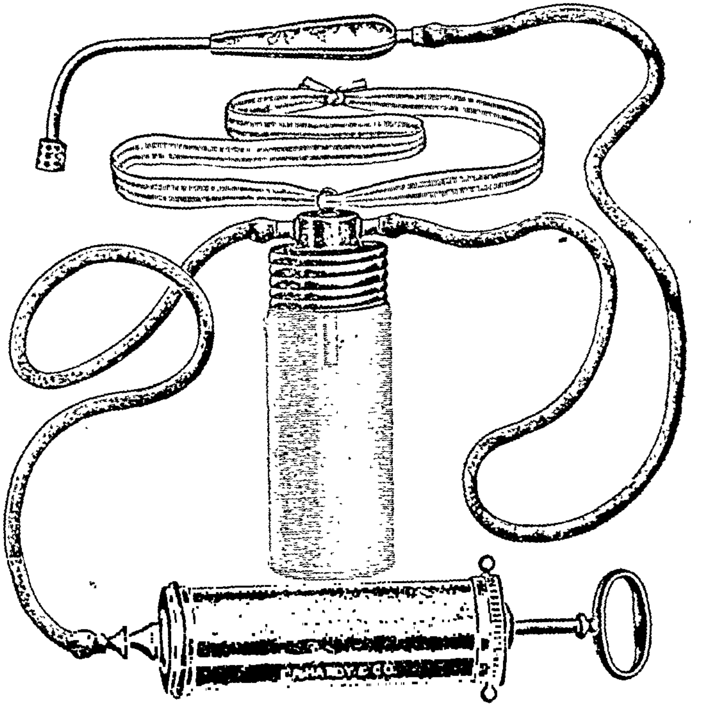

Fig. 2.—Blood aspirator.

ERYTHEMA FROM BALSAM OF PERU

H. H. HAZEN, M.D.

WASHINGTON, D. C.

Of late years there have been a number of cases reported in which balsam of Peru applied locally in scabies has caused a nephritis and it frequently sets up a dermatitis at place of application. Lewin[1] mentions a case in which 8 gm. applied locally to the arms, shoulders, and chest for scabies caused an urticaria and bronchitis. With the exception of this case I have been unable to find anything in the literature that corresponds to my case.

The patient, a white man, aged 20, had contracted gonorrhea, and a severe epididymitis shortly developed. While under treatment he noticed an itching between the fingers, which soon spread up to the wrists, and then up the forearms, being especially marked on the flexor surfaces of the elbows. The eruption appeared on the abdomen, and one or two papules appeared on the penis. The lesions appeared as papules or vesicles, which itched intensely, especially at night. The patient's physician, Dr. Craig, diagnosed scabies and recommended either sulphur or balsam of Peru. At a later date, Dr. Craig informed me that the boy had himself made a mixture of balsam of Peru and lard and had used it very freely. After the use of the ointment for one week there appeared on the face and all over the body a blotchy ill-defined eruption that itched intensely when he perspired. It is to be noted that the patient had taken no drug whatsoever internally for the gonorrhea, now almost cured; I saw him two weeks after the secondary eruption had appeared. In the interval he had thought that the scabious lesions were spreading and had been applying the ointment very vigorously and had been rapidly getting worse. He had no trace of the scabies, but was almost completely covered by a macular, ill-defined, measly eruption that was of a faint pink or purplish color. The macules were about 1 cm. in diameter and were roughly oval in shape. Over the extensor surfaces of the knees the skin was thickened and of a markedly purplish hue. There was no factitious urticaria. The eruption resembled that caused by the internal use of copaiba, except that it was paler in color. To some extent it resembled a macular syphilis, but no chancre could be found, there was no glandular enlargement, no alopecia, and no sore throat or mouth. The diagnosis of erythema from balsam of Peru was made. The urine was examined for a possible nephritis. The specific gravity was 1005, the color pale yellow, not brown as is usually the case in balsam of Peru intoxications, and contained a number of gonorrheal shreds, but no albumin that could be demonstrated by either Heller's or the heat and acetic acid test. The ring test also failed to show any resinous bodies. There were no casts and no red blood cells. I ordered the use of the balsam stopped and prescribed instead a mild lotion. Within a week the patient was well, though previously he had been getting worse steadily. The results, I think, make the diagnosis certain.

THE CRESCENDO MURMUR IN MITRAL STENOSIS

ALFRED E. COHN, M.D.

NEW YORK

Last August, Dr. E. M. Brockbank[1] published his theory of the crescendo murmur in mitral stenosis and concluded contrary to the current teaching, that this murmur was made during auricular systole (presystolic), that it occurred during the early portion of ventricular systole, possibly in the presphygmic period. Letters were subsequently published by Sir John Broadbent, Dr. Taylor and Dr. Samways criticizing Brockbank's notion from one point of view and another.

In October I reported[2] the findings in a case of mitral stenosis in which the presystolic murmur was constant and which persisted during those cycles in which there was ventricular silence, the irregularity being due probably, to digitalis poisoning. In this case the murmurs which accompanied ventricular contraction, together with the first and second sounds, were wanting, the presystolic murmur alone marking the occurrence of the cycle.

I wish to report a second case which I have been enabled to study with the permission of Dr. N. E. Brill. This also is a case of mitral stenosis, with a presystolic murmur, in which there are no cardiac irregularities. After admission to the hospital the patient was treated from time to time with tincture of strophanthus and the tincture and infusion of digitalis. During the time of the digitalis poisoning, an irregularity was noted which on analysis proved to be similar to that of the case already reported. Here also the irregularity was due to the fact that there was recurring ventricular silences. These occurred frequently after every third beat, sometimes after intervals of five and nine beats. There was no regularity in the recurrences of these ventricular silences. At the time ventricular contraction should have taken place, there was heard to mark the occurrence of a cycle only a presystolic murmur, the two heart sounds and the accompanying systolic and diastolic murmurs being wanting at these times. It will be noted in the accompanying tracings (Fig. 1 that the a-c interval is prolonged to 0.35 second. It will also be noted that the auricular systoles after the cycles in which there was ventricular silence are premature, and that the a-c interval is considerably shortened. Some days after the administration of digitalis was stopped the irregularity noted disappeared. Dr. Brill has kindly confirmed these auscultatory phenomena. This case and the one already reported seem to me to throw considerable light on the question of the production of the presystolic murmur. It would seem that, since during the time of the ventricular silence it could be demonstrated that the auricles only contracted, it is reasonable to presume against Dr. Brockbank, that an auricular systole is responsible for the production of the crescendo murmur.

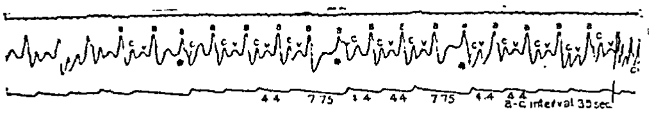

Fig. 1.—March 10, 1910. The long radial pauses are represented in the jugular tracing by a-waves only. The a-wave which follows the star (*) is premature by about 0.11 second. In this cycle also, the a-c interval is reduced from 0.35 second to 0.25 second. The upper line in both tracings represents the time in 1/5 seconds.

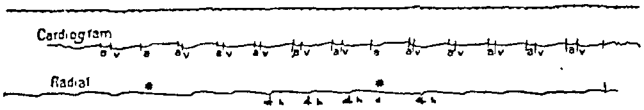

Fig. 2.—March 11, 1910. The upper curve is an inverted cardiogram; the lower is the radial tracing. The long radial pauses (*) are represented in the cardiogram by an a-wave only; a v-wave, representing ventricular contraction, is here wanting. It was in these cycles that the presystolic murmur alone, unaccompanied by first and second sounds together with their murmurs, was heard. It will also be noted that in this tracing the As-Vs interval gradually increases up to the cycle in which the a-wave occurs alone. The following cycle again shows a short As-Vs interval, 0.1 second; and gradually lengthens to 0.3 second.

Therapeutics

MERCURY IN SYPHILIS

In spite of the vicissitudes through which practical therapeutics has passed in modern times, mercury still retains its rank as the one indispensable drug in the treatment of syphilis. Attempts have been made, however, to make its use more exact, and its effects more prompt. The importance of this subject has been increased by the finding of the *Spirochæta pallida* as the probable cause of the disease, and by the discovery of the Wassermann reaction, which has shown that the syphilitic element in disease is far more frequently an important factor in guiding treatment than had hitherto been realized.

In undertaking the treatment of a case of syphilis, several questions arise which have not yet been definitely settled, or at least about which there is still room for difference of opinion.

In the chronologic history of the individual case the first therapeutic question which arises is, when shall the administration of mercury be commenced? It has been the fashion with most teachers to advise that mercury should not be prescribed until the appearance of the secondary cutaneous lesions. It is argued that it is extremely difficult to make an accurate diagnosis of the primary lesion, and that if one commences the use of mercury before the rash appears, and then, if the rash never does appear, that one cannot be sure that he has not made a mistake in diagnosis, that the patient never had syphilis, and that consequently he has unnecessarily undergone a tedious, expensive, not beneficial, and possibly absolutely injurious, treatment. It is indeed a most astonishing argument to use against a proposed treatment, that there is a not inconsiderable chance that the diagnosis may be incorrect. But the discovery of the *Spirochæta pallida*, and the growing conviction among the members of the profession that it is the cause of syphilis, has lessened the liability to error in diagnosis. Dr. H. M. Christian, of Philadelphia, in an excellent practical article on this subject (*Monthly Cyclopedia and Medical Bulletin*, January, 1910), says that he "would be disposed to put a patient on treatment at once if *spirochætæ* were found on any given lesion, but he also states that he would require pretty convincing evidence that they were actually present. He also quotes Harris (The Journal Dec. 5, 1908) as saying, "After demonstrating the organism in a primary lesion, it is not only unnecessary but harmful to wait for secondary manifestations. The most logical therapy is excision of the chancre, when possible, and in all cases the immediate institution of vigorous antisyphilitic treatment."

Having decided to commence the treatment with mercury, the next question which arises is, what preparation of the drug shall be used, and how shall it be administered? In many cases it is preferable to administer the medicine internally and the preparations best adapted for such use are the protiodid, the biniodid, the bichlorid of mercury, and mercury with chalk. The one best adapted for general use is the protiodid, which may be given in doses of 0.015 to 0.02 gram (¼ to ⅓ of a grain) three or four times a day, the smaller dose and less frequently repeated if the medicine causes too frequent movement of the bowels. This treatment should be employed constantly, even in benign cases, for at least eighteen months.

The inunction treatment is an exceedingly "efficient method of attacking the disease in its incipiency." On this point Christian writes: "At the outset of every case of syphilis, if it is at all practicable and can be done without attracting attention, I advise a course of 20 inunctions, employing 4 grams (a dram) of the official mercurial ointment, rubbed well into the different parts of the body, once a day, the treatment lasting from at least 10 to 15 minutes." While patients are under this inunction treatment, a "body bake" or, as Christian suggests, a Turkish bath at least once a week is advisable. At the end of 3 weeks Christian begins the internal administration of mercury, but thinks that it is advisable to give a course of inunctions at least 2 or 3 times during the first year in every case of secondary syphilis. If there is "marked anemia with loss of flesh, and profuse eruption threatening to appear on the face, with marked alopecia," Christian believes that internal medication is temporizing, and more strenuous measures should be inaugurated. He also believes that every patient who has recovered from all manifestations of syphilis should receive a three weeks' course of mercurial inunctions twice a year for 4 or 5 years.

A third method of administering mercury, which has been gaining considerably in favor during recent years, is that by intramuscular injection. Most writers on this subject advise the intramuscular injection to be made into the gluteal region. It is not absolutely demonstrated that this is the only place or perhaps even the best place for these injections. Dr. Henry A. Pulsford, of South Orange, N. J. (*The Journal of the Medical Society of New Jersey*, September, 1909) writes: "In selecting the point for each puncture one should be sure that the layer of muscle into which the needle is to be thrust is sufficiently thick and not too well supplied with vessels and nerves. In general we avoid the lower part of the buttock, in order that our patients may sit without undue discomfort; the vicinity of the trochanter, because the deeper tissues, being tendinous and aponeurotic, are unsuited for injection; and the center of the gluteal region, because there is a possibility of puncturing the gluteal vessels or the sciatic nerve. Our choice is consequently restricted practically to two areas on either side, each about three inches in diameter, and situated, the one just to the right or left of the intergluteal fold, and the other midway on a line connecting the upper end of the fold with the anterior superior spine of the ilium. I have made a great many injections in both of these two areas without ever wounding any important vessel or nerve, and with but little pain or discomfort to the patients."

The best syringe for these injections is one made entirely of glass, of small caliber, and graduated to fractions of a minim, such as is made for tuberculin injections. The needle should be from 1½ to 3 inches in length. Steel needles are much cheaper than those of iridoplatinum, but are likely to be corroded by soluble mercurial salts.

Concerning the administration of the injections, Pulsford further writes: "The technic as far as sepsis is concerned is the same as that observed in the injection of a therapeutic serum. The sterile fluid is drawn into the syringe, and any air bubbles carefully expelled. Then the skin having been properly cleansed, the needle is thrust through it in a perpendicular direction so as to reach the required depth at a single stroke. Next assure yourself that the point of the needle does not lie in a vein, by detaching the barrel and watching the lumen for a moment. If blood flows through the needle, make another puncture; otherwise replace the syringe and proceed with the injection. It is not necessary to massage the injected mass. The most careful practice is to make the injections with the patient lying face downward, but those well accustomed to the procedure may be properly injected standing, provided they are required to relax the gluteal muscles. The dressing of the puncture is necessary only when bleeding occurs."

The preparations of mercury used in this way includes both soluble and insoluble salts. The most useful soluble salts are the benzoate and the biniodid. These are well tolerated and efficient, and all others are superfluous, in the opinion of Levy-Bing, as expressed in his monograph on intramuscular mercurial injections, published in Paris, in 1909. The salts mentioned are used in 1 or 2 per cent. solution, in isotonic saline solution. The insoluble salts most frequently used are the basic salicylate, calomel and grey oil, the latter being an emulsion of metallic mercury in an oily vehicle. "The vehicle for calomel and the salicylate may be either an oil or a mucilage. In my experience the combination recommended by Levy-Bing of 3 parts of anhydrous wool-fat with 7 of white liquid petrolatum has proved satisfactory. It is most important that all these substances be pure and neutral. Calomel should be especially pure, and should be washed in boiling alcohol before being incorporated with the vehicle, and both calomel and mercury salicylate should be finely divided by prolonged trituration with the menstruum.

But of these preparations may be sterilized in a water-bath; the grey oil, however, is spoiled by heat and consequently must be prepared from sterile materials with sterile utensils and under aseptic conditions. As the process consists of a trituration of the mercury with the wool-fat for at least two hours, it may be imagined what a formidable task this is. If carefully guarded from contamination these injection fluids need not be repeatedly sterilized." (Pulsford)

Injections of soluble salts should be used when rapid mercurialization is required. They may be used at the beginning of treatment. The insoluble salts are indicated in the routine treatment of most cases. Calomel is usually more effective in urgent cases, but it causes too much pain to use in ordinary cases, in which the salicylate and the grey oil are preferable.

In beginning treatment it may be necessary to give an injection every day for a few days; but afterwards a weekly injection will be sufficient.

The average weekly dose is 1 grain of metallic mercury, 1 1/6 grains of calomel, or 1⅔ grains of salicylate of mercury.

Among the disadvantages of this form of treatment should be noticed the fact that they are more or less painful. With the soluble salts the pain begins at once and lasts for from 1 to 6 hours. With insoluble preparations it begins within an hour, and lasts from 2 to 5 days. The pain is most severe after calomel, and least so after grey oil, which is often entirely painless.

Hard masses of exudates, known as nodes, sometimes forms about the injected mass. These often retain a part of the injected fluid, which may subsequently be suddenly absorbed.

Embolism sometimes results from the injection of the fluid into a vein. Although this has rarely, if ever, proved fatal, it should be avoided. Abscesses rarely occur if the injections are properly administered.

The points of superiority over other methods of administration are that it enables the physician to introduce promptly into the general circulation a definite amount of mercury. It cannot be vomited, nor does it form insoluble combinations with the food or secretions, or pass through the alimentary canal and entirely escape absorption. It does not cause enteritis, nor does it become lodged in the liver, with the danger of being suddenly passed into the circulation in excessive amount. It does not cause diarrhea or loss of appetite. It has the advantage over inunctions that it does not cause irritation of the skin or dermatitis.

Intramuscular injections of mercury should not be used in patients who have excessive dental caries. Injections of insoluble salts should not be used in patients who are the victims of tuberculosis, nephritis, diabetes, hepatic disease, or cachexia. It should not be attempted to apply this treatment to patients who are unable to make personal visits to the physician at least once a week.

Whatever method of administering mercury is adopted, certain general hygienic rules must always be observed. The teeth must be put into good condition and the mouth must be kept clean. Chewing tobacco must be absolutely interdicted. Moderate smoking and temperate drinking may be allowed to those who are accustomed to the use of tobacco and alcoholic drinks, unless some special condition renders it advisable to discontinue their use entirely.

The Electrostatic Treatment of Lupus.—J. A. Voorthuis (*Proc. Roy. Med. Soc.*, February, 1910), has obtained good results in the treatment of lupus with static electricity after the method of Suchier. The process begins with thorough cleansing and disinfection of the parts to be treated. Under local or general anesthesia the tuberculous granulations are removed by strong, sharp curettes. After the bleeding has ceased and the wound has become almost dry the patient is connected with a metallic electrode in connection with the negative pole of the static machine. A pointed electrode connected with the positive pole is placed on the skin in the neighborhood of the wound and the circuit opened. Lifting the positive electrode 1 mm. from the skin the spark is seen and it is directed on every part of the wound. In five or ten minutes the wound is covered with a brownish crust, surrounded by an anemic ring of healthy skin. There is slight swelling, but this disappears in a few hours. Serum is often secreted, which should be absorbed by an aseptic tampon. The wound is then dry and no bandage is required. In a few weeks the crust is loosened and epidermization has taken place under it. A flat, pink scar is left, which in a few weeks becomes white. The application is not painful. A spot the size of a shilling requires treatment for half an hour. The cure takes much less time than the Finsen treatment. The difficulty is in removing all the granulations with the curette. It is possible also to use the spark inside the cavities of the nose and mouth, by means of a small glass tube and a copper wire. The effect must be due to the heat. By this method heat is continually created by means of proximity of wound and electrode, and it can be continued indefinitely without damage to the patient. Whether the speed of the ions, the stress of the current and the light concur in the effect is not determined.

THE AMERICAN MEDICAL ASSOCIATION—ITS POLICIES AND ITS WORK

VII. MEDICAL EDUCATION

The low educational standards which have obtained and which to a large degree still obtain in many American medical schools have long been deplored. It was not to be expected that a new and rapidly developing country like this should at once have schools of the same high grade as those found in the older countries: but there was no legitimate excuse for the fact that conditions with us were worse than in any of the other new countries—Canada, Australia, New Zealand, etc. The lack of legal restrictions in the organization and incorporation of medical colleges undoubtedly has been largely responsible for the existence of the great number of mediocre and low-grade medical educational institutions. As is well known the birth of the American Medical Association was the result of a convention called in May, 1846, to consider the subject of a higher standard of medical education. After the Association was formed, this subject was the principal topic in the annual discussions, and there are very few of the reports of the transactions that do not contain some discussion or some resolution on the subject. It would be hardly correct to say that these continued efforts of the Association accomplished nothing, since the resolutions and discussions directed attention to the deplorable conditions existing and many colleges did raise their standards, both of entrance requirements and of pedagogic efficiency. But the greater number did not raise them, and in such colleges students were admitted with little more, or even less, than a common school education; and they were graduated with the merest smattering of medical knowledge. In spite of pleas for higher standards the number of these low-grade schools increased until there were practically as many medical colleges in the United States as in all other countries combined. The attempts by the more progressive members of the American Medical Association to bring about a reform in the conditions that existed were rendered largely ineffective by the fact that the Association itself was dominated by representatives of the very institutions which needed reforming.

Such were the conditions when the reorganization of the American medical profession took place. After the reorganization, however, a new order of things was brought about. A special body was created—the House of Delegates—whose function is to transact the business of the Association; the members of this body are not direct representatives of proprietary medical colleges, but are representatives of the profession as a whole and therefore less likely to be biased in their efforts to carry out the objects of the Association.

Under these new conditions, in 1902, a committee on medical education was appointed similar to those formed in previous years but with far different results. In its report in 1904, this committee, recognizing the futility of temporary bodies, recommended the appointment of a permanent council with funds at its disposal to carry on its work. This recommendation was adopted; the Council on Medical Education was created; provision was made for the employment of a secretary who would devote all his time to the work; and an appropriation was made to meet the necessary expenses. Instead, therefore, of the short-lived, isolated efforts of temporary committees, however excellent their work, there was now an opportunity for steady continuous effort by a permanent body.

Recognizing from the first that its chief function was to obtain and publish facts regarding medical education, the Council immediately took steps to procure reliable information regarding medical standards and medical teaching institutions both at home and abroad. Lists of colleges were prepared, copies of their announcements secured and permanent files arranged; information was obtained regarding the entrance standards, the length of medical courses, the character of the college curricula and the requirements for graduation; copies of the medical laws and statements regarding the licensing of physicians in each state and in every foreign country were collected; in fact, official and reliable information bearing on all phases of medical education in this and other countries was obtained from every available source. The Council naturally took over the work, begun in 1901 by The Journal, of obtaining data regarding the number of students attending medical colleges, the number of graduates and other information relating to medical education, and published in the annual Educational Number of The Journal. It likewise assumed the responsibility of securing official statistics from state examining and licensing bodies, a work which was begun by The Journal in 1903, and on which were based the tables showing the successes and failures of medical college graduates. This matter also is published annually in the State Board Number of THE JOURNAL, of which this issue is an example.

In addition to the data regarding medical colleges in the United States, the Council also compiled the first complete list of foreign medical colleges—a list which revealed the startling fact that there were practically as many colleges in the United States as in all other countries combined. This systematic collection of educational data has been continued from year to year, with the result that an abundance of valuable information has been obtained regarding medical education, medical teaching institutions and regulations governing the licensing of physicians in this and other countries. In fact, it is no exaggeration to say that there is now more information on these topics to be found in the educational department of the American Medical Association than in any other one place. The result is that the Council is now recognized, both at home and abroad, as an important source of information regarding medical education, and requests for such information are received daily.

The collection of information, however, by no means represents the extent of the Council's activities. From time to time it appointed special committees which submitted reports on preliminary education, the granting of advanced standing for work done in colleges of liberal arts, a model medical curriculum, the character of the state license examination and the use of practical tests, a model medical practice act and other important topics. Probably the most notable of these was the special committee on medical curriculum consisting of one hundred leading medical educators of the United States, assisted by a large number of other leaders in medical education acting in an auxiliary capacity.

Another important feature of the Council's work has been an annual conference on medical education which has been largely attended by members of the state licensing boards, by delegates of state medical associations, by officers of the United States governmental services and by representatives of medical colleges, universities and educational organizations, every section of the country being fully represented. At these conferences the Council presented reports of its work, calling particular attention to conditions of medical education and medical registration in the various states. These conferences have furnished an opportunity for a thorough discussion of all reports and methods of procedure and have been of great value to the Council in the formulation of its standards.

The most important work of the Council, however, is yet to be described. Almost at the outset it became evident that medical college catalogues and announcements, as a rule, could not be relied on to reveal actual conditions or to furnish data on which standards could be based. It was decided, therefore, to inspect, personally, all colleges and thus to obtain information at first hand. After the preparation of an outline of the points to be considered in the study of each college, this work of inspection was begun and during the college session of 1906-7, the personal inspection—the first ever made by any organization of all the medical colleges in the United States—was completed. Since then a second tour of inspection, which included the medical schools of Canada also has been completed. The conditions revealed by these inspections were far from creditable to the schools as a whole. Although a number of high-grade, fully equipped and excellently conducted medical colleges were found, there were many which were seriously deficient both in the quality and in the amount of work done. Several were found devoid of laboratory and clinical facilities, the sole equipment in some instances being a desk, a typewriter and some chairs. In some of the larger colleges the didactic curriculum of thirty years ago was being continued; instead, however, of giving the same course of lectures to two classes in two separate years they were now giving the same course to four classes in four separate years.

The collection, and, still more, the publication of these educational data, have had a tremendous effect on the standards of medical education. The publication of facts regarding medical licensure in the various states has aided in the movement toward higher, more uniform and more effective laws and methods in the licensing of physicians. The publication of statistics regarding tuition fees of colleges has answered the "poor boy" argument so frequently used as an excuse for conducting low-grade colleges. It has been shown that, for the same or even for less money than he would pay in a low-grade college, the student could secure a thorough training in a good, well-equipped medical school. The Council has shown that in practically every other country, thorough courses in the pre-medical sciences are required of every prospective medical student. The result of the publishing these facts has been that instead of only three medical colleges which require for matriculation a preliminary education in advance of the ordinary high-school course, there are now twenty-four having that requirement; and by the beginning of the next college session this number will doubtless be increased to forty or more. In addition seven state licensing boards now insist that applicants shall have had one or two years of college work preliminary to their medical course.

The publication of statistics showing the unsatisfactory conditions has had much to do with the rapid reduction in the number of medical colleges. This has fallen from 166 to 132, although it must be admitted that the decrease in the demand for physicians has also had considerable influence. As a result of the mere publication of actual conditions, several colleges voluntarily have closed their doors in order that higher standards and improved methods of teaching might prevail and a number have been closed by the action of state licensing boards. A greater reduction in the number of schools, however, was through voluntary mergers in several cities of two or more colleges, forming in each instance one stronger and better equipped college. By this process of merging, in the last six years *forty-four* colleges have been replaced by nineteen institutions of higher grade.

The chief function of the Council, as already stated, is to obtain and to publish facts regarding medical education; and such publicity can result only in good to medical education in general. There is no desire to criticize any individual college for the Council fully recognizes the difficulties against which individual colleges have had to contend in their efforts to make improvements. It is encouraging to note that the majority of colleges have welcomed investigation, have invited a publication of the facts, and have greatly aided the Council in its work. It is to be regretted, however, that some medical colleges remain which may not welcome the presentation of facts and which may be injured thereby. We may apply to this educational situation what President Taft recently said of the commercial world: All business should be made legitimate so that laws for the general good will not injure that business. Similarly it may be said that those colleges which fear [illegible]ity should make such improvements in their methods and equipment that the publication of facts will not injure them. Curiously enough, some of the lowest-grade medical colleges inspected by the Council were, in the opinion of their deans, "the best in the country," which points the truth of a statement made recently by the United States Commissioner of Education,[1] that the people not only need protection against those who use false pretenses in the realm of education but also against those who *offer an inferior grade of instruction, under the delusion that it is as good as the best.* "The *well-meaning* no less than the dishonest [illegible] some impartial test by which their educational tio[illegible] [illegible]oved, of what sort it is."

tering [illegible] to be done and while there are higher [illegible] deficient medical schools, increased [illegible] has been decidedly colleges in th[illegible] **few years.** [illegible]ce requirements combined. The a[illegible] **better enforced**, college terms have been lengthened, new buildings and hospitals have been erected, new laboratories have been added and old laboratories better equipped, libraries and museums have been developed, a much larger number of expert, full-time salaried instructors has been secured and better methods of teaching have been adopted. In fact, so many have been the improvements in medical education as to warrant the assertion that more has been accomplished in the past six years than in all of the previous sixty years of the Association's existence; and it is gratifying in the extreme to those who have long struggled and pleaded for higher and better standards of medical education to see, at last, so much already accomplished and the outlook so bright for still greater things in the future.

bers of the American [illegible]

a reform in the condi[illegible]

Of course this work has created some opposition to, and in a few cases active antagonism against the American Medical Association. Exposing the weakness of some institutions affected powerful interests and, naturally, friction resulted. In the vast majority of cases, however—and this is but another illustration of the altruism that pervades the medical profession—the very evident need of such changes has been recognized and the efforts of the Council on Medical Education have been heartily endorsed and its work materially aided.

A MONUMENT TO MEDICAL HEROES

An article entitled "The Public's Forgetfulness," in the *Outlook*, Aug. 11, 1906, called attention to the heroic character and beneficent results of the work of the Army Yellow Fever Commission in Cuba in 1900, and urged some recognition by the nation of the achievement and of the courage of those who had submitted to experimental infections in the course of these investigations. This article attracted the attention of President Roosevelt, who, after obtaining a full and authoritative report on the subject from the War Department, sent a message to Congress which was probably the briefest he ever wrote. It was as follows:

> THE WHITE HOUSE, Dec. 5, 1906.
>
> *To the Senate and House of Representatives:*—The enclosed papers are transmitted to the Congress in the earnest hope that it will take suitable action in the matter. Major Reed's part in the experiments which resulted in teaching us how to cope with yellow fever were such as to render mankind his debtor and this nation should in some proper fashion bear witness to this fact.
>
> THEODORE ROOSEVELT.

Senator Owen of Oklahoma, who has already given evidence of his interest in a matter of great practical importance to the public weal by advocating the creation of a department of health, has now shown himself equally appreciative of educational and moral values by the introduction of a bill (S. 8024) which will put into execution the recommendation of that message. It appropriates the sum of $50,000 for a statue in Washington "in honor of the Yellow Fever Commission composed of Major Walter Reed, Surgeon, U. S. Army, Dr. James Carroll, Dr. Jesse W. Lazear and Dr. Aristides Agramonte, Acting Assistant Surgeons, U. S. Army, and the placing on the pedestal a bronze tablet in memory of the men who consented and assisted by the voluntary exposure of their persons in making the experiments which resulted in the discovery of the means whereby yellow fever is disseminated; the site to be selected and the pedestal and statue to be erected by and under the supervision of a commission composed of the President of the American Medical Association, the Secretary of War, Major-General Leonard Wood, U. S. Army, the Surgeon General, U. S. Army, and Colonel William C. Gorgas, Medical Corps, U. S. Army."

Congress has erected in the Capital City many statues to celebrated Americans, and the generous foreigners who assisted in our war for independence have not been forgotten. These have been chiefly men of the sword, and no man whose mission has been the saving of life, has been as yet so honored by our national legislature, although by private subscriptions statues have been raised to Rush, to Cross and to Hahnemann.

The time seems ripe for this action, as a decade has now passed since the commission published its findings to the world and all of them have been fully accepted by scientific men. Three of the members of the commission are dead; the fourth, Dr. Agramonte, is a distinguished professor in the university of Havana.[1]

It is pleasing to see that the proper interest of the American Medical Association in the erection of this monument is recognized by the naming of its president as the head of the commission to which the execution of the work is entrusted.

COLLECTION AND VALUE OF STATE BOARD STATISTICS

We present this week tabulated statistics based on examinations conducted by State Medical Examining and Licensing Boards. With the exception of one report from Alabama, for which the list of failures could not be obtained, the returns are complete. The four large tables, A, B, C, and D, give the results in detail, while tables E to M, inclusive, give important deductions from these tables. Table M gives the totals registered by each board by all methods, examination, on credentials, through reciprocity and otherwise, while Table N shows the registrations by reciprocity.

Tables I, J and K give the various medical colleges classified according to the percentage of failures (below 10 per cent., between 10 and 20 per cent. or above 20 per cent.). Although no positive conclusion can be formed in regard to any college on the basis of these statistics alone, nevertheless the deductions which they invite are surprisingly in agreement with the conclusions resulting from the thorough investigation and inspection of medical colleges conducted during the past five years by the Council on Medical Education. The fact that a few medical colleges of inferior grade, conducted largely by quiz-class methods, succeed in obtaining low percentages of failures and appear in Table I, points towards the necessity of changing the character of the state license examination so that actual knowledge—not theoretical knowledge obtained by "cramming"—shall be necessary to pass it.

These statistics are of great value and throw much light on several factors in medical education and medical licensure. The publication of the failures of graduates of the colleges has stimulated the colleges to better work, and efforts have been made to find and strengthen the weak places in their courses of instruction. The very fact that the reports are called for regularly has tended to unify the various systems of records kept by state licensing boards, while in some states records are now kept whereas previously they were not.

Furthermore, from the official data regarding medical college graduates, the Council on Medical Education, which now has charge of the collection and tabulation of these statistics, has been able to check up the state board reports, thereby rendering the tabulated statistics more accurate, making it certain that failures at examinations are not charged against the wrong college, and insuring a greater accuracy of state records. These statistics, therefore, not only have helped in the betterment of medical education, but also have led to the adoption of more uniform methods of record-keeping in the various states. Before THE JOURNAL began the publication of these statistics the accurate information, which can now be readily obtained, concerning the number of physicians registered each year in each state or in the United States was not anywhere available.

Probably no one has recognized the value of these statistics more than the state licensing boards themselves, who, through the furnishing regularly of carefully prepared reports have made possible the publication of this valuable information.

IMPROVED MEDICAL EDUCATION AT ST. LOUIS

Another evidence of the rapid improvement of medical education in this country is found in the action of the directors of Washington University, St. Louis, in reorganizing its medical department on a broad, strong basis. This action has been made possible by the union of a large general hospital and of a children's hospital with the medical school, and by gifts for medical, laboratory and clinical buildings aggregating, with the endowment, over six million dollars. The principal contributors to the endowment are Adolphus Busch, William K. Bixby, Edward Mallinckrodt and Robert S. Brookings.

---

[1] Any one who is interested and desires to know all the facts relative to the work of the Yellow Fever Commission should obtain from his congressman or senator a copy of the document (Senate Document No. 520, 61st Congress, 2nd Session) which accompanied the introduction of the bill. This pamphlet contains the president's message and accompanying documents, including valuable official data.

A large tract of land at the east end of Forest Park has been secured, on or near which all the hospital and college buildings will be erected. In addition to the general hospital and the children's hospital it is proposed to erect laboratory and clinical buildings with dispensary facilities, and within a short time also a maternity hospital. It is stated that all hospitals are to be fully used for teaching purposes, the relation to be substantially the same as that which exists between the hospitals and the medical school of the Johns Hopkins University. New buildings throughout of modern construction and arrangement have been planned.

The university is to select the medical staffs of the hospitals and is seeking the ablest men for the leading chairs of the college. Among those already selected are: Dr. George Dock, formerly of the University of Michigan, now of Tulane University, New Orleans, for the chair of medicine; Dr. John Howland, of the University and Bellevue Hospital Medical College, New York, and a member of the Council on Pharmacy and Chemistry of the American Medical Association, the chair of pediatrics; Dr. Eugene L. Opie, pathologist at the Rockefeller Institute of Medical Research, the chair of pathology; and Dr. Joseph Erlanger, of the University of Wisconsin, the chair of physiology. The selection of men for the chairs of surgery, medical chemistry, preventive medicine and pharmacology is proposed in the near future and also of a number of able permanent assistants and a large and strong staff for supplementary teaching work and for the dispensary and hospital service. All the men who have been added to the faculty are to assume their duties within a year.

It is significant that the entrance requirements are not to be extreme. Beginning this fall one year of collegiate work will be required in addition to a four year high school education and this by the fall of 1912 will be further increased to two years of collegiate work. The plan to have all buildings, laboratory, clinical, hospitals and dispensaries, in one group and of easy access as well as the character of the men being selected to fill the various chairs give promise of a medical college of the first rank. Furthermore the location of a school of this character in St. Louis is sure to have a profound influence on medical education throughout the middle West and the South. Finally this generous provision for the development of medical education at Washington University is another encouraging indication that men of wealth are awakening to the necessity of endowments for medical education.

Prognosis in Appendicitis in Children.—The prognosis of appendicitis in children is influenced very materially by a number of factors; *e. g.*, age, difficulty in diagnosis, rapidity of its progress, delayed operation, and the lessened resistance to bacterial invasion on the part of very young children. Next to delay, age [illegible] more than any other factor, determines the outcome. [illegible]reased [illegible]ger the child, the worse the prognosis. —J. M. T. Fi[illegible] *Dominion Journal of Medicine and Surgery* [illegible]ber, 1909.

Medical News

CALIFORNIA

Cooper College Graduates.—On May 5, the annual commencement exercises of Cooper Medical College, San Francisco, were held, and a class of seventeen was graduated. Dr. Henry Gibbons, Jr., dean of the college, introduced the president, Dr. Edward R. Taylor, who conferred the degrees.

Personal.—Dr. Charles V. Cross has been appointed president; Dr. Thurlow S. Miller, secretary, and Dr. Edwin C. Van Dyke, treasurer, of the reorganized Board of United States Examining Surgeons for San Francisco.——Dr. George L. Cole has been appointed a member of the board of health of Los Angeles, vice Dr. William J. Chambers, resigned.

Hospital Notes.—With the completion of the group of county hospital buildings, Los Angeles County will have expended $300,000 in this work. The completed buildings will contain an administration building, surgical ward, three medical wards, tuberculosis building, contagious ward, insane ward, nurses' quarters, superintendent's residence, etc. At present there are under construction an additional story to the lecture hall, a twenty-room additional building for nurses, and a new operating pavilion and a chapel.——The Mills heirs have given $1,000,000 for the endowment of St. Luke's Hospital, San Francisco.——Two hundred women of Oakland, Alameda and Berkeley, on May 2, began a ten-day campaign under the direction of the King's Daughters of California to raise $100,000 by popular subscription, with which to erect and equip a new building for the home for incurables.

ILLINOIS

Physician Goes to Prison.—Dr. William H. Miller, convicted of the murder of John Saylor, Crescent City, and sentenced to twelve years' imprisonment in the state penitentiary, was taken to Joliet, May 10, to begin his sentence.

Hospital Notes.—Work on the annex of St. Vincent's Hospital, Taylorville, began April 28. The annex will contain a maternity ward of five rooms, and will increase the capacity of the hospital to a total of seventy.——Rockford Hospital, in its report for the year ended January 1, announces that it closed with a deficit of about $1,500, most of which was made up of outstanding obligations of patients.

Chicago

Personal.—Dr. Henry R. Harrower, formerly editor of the *Medical Standard*, has severed his connection with that journal, and is now conducting a new periodical, the *American Journal of Physiologic Therapeutics*.

College Merger.—It is reported that a merger has been completed between the Bennett Medical College and the Illinois Medical College, the latter of which recently became the Medical Department of Loyola University. The new school will retain the name of the Bennett Medical College.

Chicago Tuberculosis Institute.—A new medical building has been opened at Edwards Sanatorium, Naperville, Ill., a department of the Chicago Tuberculosis Institute. The sanatorium at present consists of a forty-acre farm, with a general administration building, medical building, six open-air shacks and individual tents. The institution, at present, can accommodate sixty patients.

More About the Diploma Mill.—At the instance of the State Board of Health, Dr. Alexander Chittick, secretary of the "Chicago Medical University," E. J. Barnes, and N. O. Bourque, associated with Dr. Chittick in the "Crescent Medical University," were arrested, May 13, charged with fraudulent use of the mails. The defendants were taken before United States Commissioner Foote, their case was set for hearing May 23, and they were released on bail. It is claimed that these institutions, which are said to exist only on paper, sell diplomas in medicine, pharmacy, dentistry, osteopathy, etc., at prices ranging from $6 to $40.

Ricketts Memorial Service.—A memorial service for Dr. Howard Taylor Ricketts, assistant professor of pathology in the university, was held in the Leon Mandel Hall, University of Chicago, May 15. Dr. Henry Pratt Judson read a letter from the Bureau of Education of Mexico expressing appreciation of the work of Dr. Ricketts, and mentioning the honors conferred on him. He also made a brief address on the work of Dr. Ricketts, and the essential facts of his life and death were given by Dr. Russell M. Wilder, who was associated with Dr. Ricketts in his work in Mexico. Dr. Ludvig Hektoen delivered an address on the personality of Dr. Ricketts and the nature and value of the work. Prof. Charles Henderson of the University spoke on the humanitarian aspects of Dr. Ricketts' work and his death. The meeting was largely attended.

IOWA

Women's Medical Clinic.—A free daily clinic has been established by women physicians and club women of Des Moines in the Century Building, under the charge of women physicians of the city.

Society Meetings.—At the annual meeting of Tama County Medical Society, held in Toledo April 12, Dr. Walter J. McEvilly, Dysart, was elected president; Dr. Arthur A. Pace, Elberon, vice-president; Dr. William C. Wagner, Traer, secretary-treasurer, and Dr. Thomas L. Thomson, Toledo, delegate to the state society.——At the annual meeting of the Southeastern Linn Medical Association, held in Mount Vernon, April 12, Dr. Calvin G. Stookey, Mechanicsville, was elected president; Dr. Francis F. Ebersole, Mount Vernon, vice-president, and Dr. Kate Mason Hogle, Mount Vernon, secretary-treasurer.

KANSAS

Personal.—Dr. George L. A. Hamilton, Kansas City, has gone abroad.——Dr. G. D. Pendell has located in Wellington.——Dr. Harry A. Vincent, Perth, has gone to Florida for two months. ——Dr. Edwin T. Shelly, Atchison, is reported to be seriously ill with erysipelas.

State Society Meeting.—At the forty-fourth annual meeting of the Kansas Medical Society, held in Topeka, May 4-6, under the presidency of Dr. Oliver J. Furst, Peabody, the subject of whose address was "Public Knowledge of the Medical Profession," the following officers were elected: President, Dr. O. Portis Davis, Topeka; vice-presidents, Drs. Millard F. Jarrett, Fort Scott; George W. Jones, Lawrence, and John T. Axtell, Newton; secretary, Dr. Charles S. Huffman, Columbus (reelected), and treasurer, Dr. Lewis H. Munn, Topeka.

KENTUCKY

Personal.—Dr. J. A. Boyd, Paducah, was shot in the arm and painfully wounded by Dr. Charles E. Purcell during an altercation recently.——Dr. John W. Pendley, Paducah, county physician of McCracken county, was stricken with cerebral hemorrhage while attending his sister at Spencer, S. D.

Wins Suit Against College.—In the suit brought by Dr. Harry A. Davidson against the Hospital College of Medicine, in which he sought the cancellation of notes amounting to $3,000, which he had pledged himself to pay, in consideration of receiving the chair of physiology and diseases of women, and an interest in the property of the school, the judge is said to have decided that the college must cancel the notes.

LOUISIANA

Permit for Hospital.—The city council of New Orleans has granted a permit to the Colored Baptist Sanitarium to operate a hospital at 122 South Howard street.

Asks Additonal Inspectors.—Dr. William T. O'Reilly of the city board of health of New Orleans, has asked for an appropriation of $12,800 for the employment of more inspectors and to enable the board to enforce the mosquito screen ordinance.

House of Delegates Meeting.—The annual meeting of the House of Delegates of the State Medical Society was held May 2. A new constitution and by-laws was adopted. Dr. John Callan, New Orleans, was elected president, and Dr. Joseph D. Martin, New Orleans, secretary.

State Medical Society Meeting.—The thirty-first annual meeting of the Louisiana State Medical Society was held in New Orleans, May 3-5. On the first day symposia on dysentery and uncinariasis were held. At the evening session pellagra was discussed. The following officers were elected: Dr. Edwin J. Graner, New Orleans, president; Drs. Allan C. Eustis, Abbeville, Homer Dupuy, New Orleans, and Samuel A. Ayo, Thibodeaux, vice-presidents; Dr. Joseph D. Martin, New Orleans, secretary; Dr. Charles C. Bass, New Orleans, treasurer (reelected), and Dr. Isaac J. Newton, Monroe, councilor. The next meeting will be held in Shreveport.

MARYLAND

State Board of Health Election.—At the annual meeting of the State Board of Health, Dr. William H. Welch, Baltimore, and all the other officers were reelected. Dr. Marshall L. Price, secretary of the board, was selected as delegate to the American Medical Association.

Personal.—Dr. Frederick N. Nichols, Denton, has been appointed health officer of Caroline county.——Dr. Edward R. Trippe has been appointed health officer of Easton, and Dr. Philip L. Travers, physician to the county jail, Easton.——Dr. John E. Legge, Oakland, while cranking his automobile recently, fractured his arm.——Dr. Charles F. Goodell, Frederick, has been reelected health officer of Frederick county.——Dr. Elmer C. Kefauver has been elected town physician of Thurmont.——Drs. Lewis K. Woodward and Jesse S. Meyers have been elected members of the city council of Westminster.

Baltimore

Hospital News.—Through the efforts of the managers and auxiliary, $18,000 of the mortgage on the Johns Street Hospital for Women of Maryland have been paid off. An indebtedness of $22,000 still remains.

Dispensary Election.—At the annual meeting of the Baltimore Eastern Dispensary, May 9, Dr. Robert S. Kirk was elected superintendent for the twelfth time. Dr. John Roth was elected assistant superintendent, Dr. Daniel W. Cathell, vice-president, and Dr. Frank C. Bressler, a director.

Personal.—Lieutenant Howard E. Ashbury has been promoted to captain in the medical corps of the Maryland National Guard, and Drs. William P. Morrill and Lloyd P. Shippen have been appointed lieutenants and assistant surgeons.——Dr. Hugh H. Young has been elected secretary of the trustees of the new negro hospital for the indigent insane.

MASSACHUSETTS

Personal.—Dr. Frederick L. Hills, superintendent of the Massachusetts State Sanatorium, Rutland, has resigned to accept the superintendency of the Eastern Maine Insane Hospital, Bangor.——Dr. Francis X. Mahoney, Dorchester, has been appointed health commissioner of Boston.

State Society Meeting.—The one hundred and twenty-fifth annual meeting of the Massachusetts Medical Society will be held in Boston, June 7 and 8. The Shattuck Lecture will be delivered by Dr. Frederick H. Gerrish, Portland, Maine, on the "Crusade Against Syphilis and Gonorrhea," and the annual discourse will be delivered by Dr. John C. Munro, Boston.

MICHIGAN

Personal.—Dr. John L. Burkart, for a number of years acting assistant surgeon U. S. Army, with Philippine service, has opened an office in Big Rapids.——Dr. John A. Keho, Bay City, has been appointed a member of the board of health, vice Dr. William R. Ballard, resigned.——Dr. Clarence B. Wasson has been appointed health officer of Bellevue, vice Dr. Albert S. Wilson.——Dr. Perry M. Schurtz, retiring president of the board of health of Grand Rapids, was presented on May 5 with a diamond ring and set of cuff-links by the members of the board of health.——Dr. Earl V. McComb has been appointed health officer of Menominee.——Dr. A. Henri Cote has been elected city physician of Port Huron.——Dr. Victor C. Vaughan, dean of the Medical Department of the University of Michigan, was the guest of honor at a dinner of the University of Michigan Kansas City Club, May 2.

MISSOURI

Library for Medical Society.—The library of the late Dr. Jonathan E. Tefft, Springfield, has been presented by Mrs. Tefft to the Greene County Medical Society.

Southeastern Physicians Meet.—The Southeastern Missouri Medical Association met in Morehouse, May 3 and 4, and elected the following officers: President, Dr. Oba Haley, Fredericktown; recording secretary, Dr. William S. Hutton, Illmo; corresponding secretary, Dr. Thomas C. Allen, Bernie, and treasurer, Dr. William R. Goodykoontz, Caledonia.

Southwestern Physicians Elect.—At the annual meeting of the Southwestern Missouri Medical Association, held in Springfield, April 28 and 29, the following officers were elected: President, Dr. William J. Rabenau, Fordland; vice-presidents, Drs. Oscar N. Carter, Republic, and James E. Dewey, Springfield; secretary, Dr. Herbert S. Hill, Springfield, and treasurer, Dr. Lee Cox, Springfield, the two latter being reelected. Dr. James E. Loafman, Bolivar, delivered the oration on medicine, and Dr. Benjamin F. Fortner, Springfield, the oration on surgery.

St. Louis

Commendatory Resolutions.—The St. Louis Medical Society has adopted resolutions commending the council and house of delegates and mayor for the passage and signing of bills changing the management of the city eleemosynary institutions.

Hospital Merger.—The merger is announced of the Martha Parsons Hospital with the St. Louis Children's Hospital. The new institution will form part of the hospital group of Washington University Medical School, and will be housed in a new building on Kingshighway, valued at $125,000.

MONTANA

State Meeting.—The thirty-second annual meeting of the Montana State Medical Association was held in Hunter's Hot Springs, May 11 and 12, under the presidency of Dr. Thomas D. Tuttle, Helena. The officers elected were: President, Dr. William F. Cogswell, Livingston; vice-presidents, Drs. Thomas C. Witherspoon, Butte; Irvin, Great Falls, and Oscar M. Lanstrum, Helena; secretary, Dr. Herbert D. Kistler, Butte (reelected; treasurer, Dr. Creswell T. Pigot, Butte (reelected); delegate to the American Medical Association, Dr. Thomas D. Tuttle, Helena, and alternate, Dr. Thomas C. Witherspoon, Butte. Butte was selected as the next meeting-place.

NEW YORK

Is Christian Science Healing Forbidden?—An amendment to the New York state medical law which was rushed through the assembly May 5, is giving the Eddyites considerable alarm. The bill passed three years ago allowing only registered physicians to practice medicine had this exception, "This article shall not be construed to affect the practice of the religious tenets of any church." In the recent amendment introduced by Assemblyman Wilkie of Erie this exception is made to read, "This article shall not be construed to affect the practice of circumcision as the religious tenet of any church." The Eddyites are making strenuous efforts to stop this bill in the senate.

New York City

Import Measles.—The steamship *Carpathia* of the Cunard line recently arrived from the Mediterranean with 40 cases of well-developed measles among her 2,200 steerage passengers. Only the children in the steerage were affected. A few months ago a German steamer arrived with 130 cases of measles on board.

Personal.—The reception that was to have been given to Dr. John J. McPhee by the Canadian Society of New York has been indefinitely postponed on account of the death of King Edward.——Dr. Roswell Park, who has been ill with pneumonia in this city, has recovered sufficiently to return to his home in Buffalo.——Dr. and Mrs. George Woolsey and Dr. Howard S. Paine, Glens Falls, have gone to Europe.

Resolutions Regarding Dr. Goelet.—At the meeting of the Clinical Society of the New York School of Clinical Medicine, held May 3, resolutions were adopted regarding the death of Dr. Augustin H. Goelet, for more than twenty years a member of the faculty of the institution, setting forth the high qualities of Dr. Goelet, paying a last tribute to his memory, and extending to his bereaved family the sincere sympathy of the society.

Buffalo

Fronczak to Go to Paris.—Expenses not to exceed $350 were voted Health Commissioner Francis E. Fronczak by the board of aldermen to attend the International Congress on School Hygiene in Paris, August 2-7.

NORTH DAKOTA

State Society Meeting.—The annual meeting of the North Dakota Medical Association was held in Grand Forks, May 10 and 11, under the presidency of Dr. John E. Countryman, Grafton. The following officers were elected: President, Dr. Henry H. Healy, Grand Forks; vice-presidents, Drs. Clinton E. Spicer, Litchville, Alexander J. McCannel, Minot, and Murdock MacGregor, Fargo; secretary, Dr. Hezekiah J. Rowe, Casselton (reelected); treasurer, Dr. Frank J. King, St. Thomas, and councilors, Drs. Paul Sorkness, Fargo; William F. Sihler, Devils Lake, and Robert D. Campbell, Grand Forks.

OHIO

State Association Meeting.—The Ohio State Medical Association at its sixty-fifth annual meeting, held in Toledo, May 11-13, under the presidency of Dr. Walter H. Snyder, Toledo, who in his annual address, recommended greater participation of physicians in the general life of the community, education of the public in sanitation, and changes in the supervision of state hospitals for the insane. The following officers were elected: President, Dr. Arthur J. Skeel, Cleveland; vice-presidents, Drs. Samuel P. Fetter, Portsmouth; Edgar J. March, Canton; Anderson T. Spear, Newark, and James O. Starr, Pittsburg; member of the National Legislative Council, Dr. Benjamin R. McLellan, Xenia; councilor, Second District, Dr. Robert H. Grube, Xenia, and delegates to the American Medical Association, Drs. George M. Todd, Toledo; Benjamin H. Blair, Lebanon; Dana O. Weeks, Marion; B. Frank Barnes, Newark, and John W. Clemmer, Columbus. On the night of the eleventh, a one-act comedy written by Dr. Dan Millikin, Hamilton, was presented at Zenobia Theater before the association. This is commented on in the Correspondence Department in this issue. A resolution was adopted asking the state legislature to enact a law for the sterilization of habitual criminals. The next meeting of the association will be held in Cleveland. A report of the scientific proceedings will be commenced in THE JOURNAL next week.

OKLAHOMA

Graduation Exercises.—The annual commencement exercises of Epworth College of Medicine, Oklahoma City, were held May 12, when a class of 7 was graduated.

Public Drinking Cup Abolished.—Beginning May 1, the State Board of Health abolishes the public drinking cup. Violation is made a misdemeanor punishable by a fine of from $10 to $30, or by imprisonment for thirty days in jail, or both.

Faculty Election.—At the meeting of the Board of Regents of the University of Oklahoma School of Medicine, Norman, April 13, Dr. Charles S. Bobo, Norman, was elected dean, and Drs. L. W. Curley, B. F. McLaren and Walter L. Capshaw, Norman, were elected members of the faculty.

State Society Meeting.—The eighteenth annual session of the Oklahoma State Medical Association was held in Tulsa, May 10-12, under the presidency of Dr. Walter C. Bradford, Shawnee. The following officers were elected: Dr. David A. Myers, Lawton, president; Drs. Charles L. Reeder, Tulsa, H. Marion Williams, Wellston, and James L. Shuler, Durant, vice-presidents; Dr. Claude A. Thompson, Muskogee, secretary (reelected), and Drs. W. E. Wright, Tulsa, and Charles R. Hume, Anadarko, delegates to the American Medical Association.

PENNSYLVANIA

Hospital Annex Opened.—The Phoenixville Hospital opened its new $25,000 annex, April 30, thus increasing the hospital's capacity to 75 patients. The annex was made possible by the gift of $12,000 by the late Joseph Anderson, Toughkenamon.

Milk Dealer Fined.—O. H. Walters, a milk dealer of Lower Pottsgrove, was fined $75 and costs May 13, for violating the state quarantine laws during the prevalence of scarlet fever in his house. It was charged that 16 cases of the disease resulted because he sold milk before the quarantine was lifted.

Antispitting Sign to be Used.—Pennsylvania's recommendation, made through her Health Commissioner, Dr. Samuel G. Dixon, for a uniform antispitting sign to be used in railroad coaches passing through different states, was adopted April 29, by the Conference of State and Provincial Boards of Health at Washington, D. C.

Philadelphia

Addition to Philadelphia Hospital.—The first of the new additions to the equipment of the Philadelphia General Hospital, the annex to the Nurses' Training School, was opened May 12. It is of brick and has accommodation for 40 nurses.

Chair of Surgery Endowed at Jefferson.—The trustees of Jefferson Medical College announced, May 11, a gift of $60,000 from Mrs. Maria Gross Horwitz, daughter of the late Professor Samuel D. Gross, to endow the "Samuel D. Gross Chair of Surgery."

Additions to University.—May 12, ground was broken for a group of laboratory buildings for the University Hospital, on the university campus, south side of Pine street, east of Thirty-seventh street. The total cost will be $37,000. The plans provide for a series of one-story buildings.

Fire in Laboratory.—A fire in the chemical laboratory of the Medico-Chirurgical College caused great damage in three-quarters of an hour and frightened many patients. About $50,000 worth of apparatus was ruined by fire and water and the total damage will amount to more than $75,000.

Gross Prize Awarded.—The Samuel D. Gross Prize of the Philadelphia Academy of Surgery for 1910, amounting to $1,500, has been awarded to Dr. Astley Paston Cooper Ashhurst of Philadelphia for his essay entitled "An Anatomic and Surgical Study of Fractures of the Lower End of the Humerus."

Tribute to Dr. Tyson.—As a farewell tribute to Dr. James Tyson, professor of medicine at the University of Pennsylvania, 300 students of the medical department gathered in his lecture room on May 13, and presented him with a silver loving-cup and large silver platter, gifts of the members of the two upper classes. It was the occasion of Dr. Tyson's last lecture and instead of an everyday class room he found the place decorated with red and blue bunting.

Personal.—Dr. Albert Magnus-Levy, of Berlin, Germany, was the guest of honor at a banquet at the Bellevue-Stratford, May 13, following his address before the College of Physicians.

Dr. George E. de Schweinitz was the host of the occasion and covers were laid for twenty-eight guests.——Dr. R. Tait McKenzie has been appointed a representative of the United States at the Third International Congress on Physical Education to be held in Brussels, Belgium, from August 10 to 13.——Drs. F. Hirst Maier, Alfred Heineberg and P. Brooke Bland have been appointed associates in gynecology in Jefferson Medical College.

Crusade Against Doped Medicines.—Christopher Koch, vice-president of the State Pharmaceutical Board, announced, May 2, that the future activities of that board would be directed against "patent medicines" with dope in them. Soothing syrups will be one of the leading points of attack, and samples have already been sent to Professor Charles H. LeWall, chemist for the board, to be analyzed. To the general use of these soothing syrups (among babies) Dr. Koch attributes the craving for cocain and other drugs among adults, who have been indulged with these syrups during infancy. Samuel M. Clement, Jr., counsel for the board, says that the traffic in cocain in this city has now been practically annihilated and that the board would now turn its efforts to obtain federal regulation of the sale of cocain, morphin and other ruinous drugs. Five more cocain prisoners were arraigned before Magistrate Beaton in City Hall, May 2.

Baby-Saving Campaign.—To concentrate the charitable forces of the city into one big child-saving campaign, a conference of nearly 200 social workers was held in the mayor's office at City Hall on May 13. A movement was started by Dr. Jesse Burke, of the Bureau of Municipal Research, to form a central committee to report the scope, limits and activity of every charity in the city. This committee will form the nucleus of a centralized registration bureau leading to the formation of a municipal bureau of child hygiene. It was shown that lack of cooperation among the various charitable organizations resulted in the city's deserving poor not receiving the benefit of funds given for their relief and of the societies being imposed on. A little over a year ago there was organized an alliance for the care of babies under the auspices of the Department of Public Health and Charities, Board of Education, Mothers' Congress, Home and School League and allied societies, for the purpose of instituting lectures, and giving practical instruction and demonstration, by means of the lecture rooms in the schoolhouses, instituting milk depots, etc., but unfortunately public education through the newspapers did not reach the particular class of people desired. The circulars left at the home frequently remained unread and the lectures reached only comparatively few. Milk dispensaries cannot be attended by the mother who has many children. The keynote of the proposition lies in the visitation of the home by trained workers, and one object of the present crusade is the part to be played by the Bureau of Municipal Research, under the guidance of Dr. Burks, who has volunteered to supply a selected section of the city with a corps of trained nurses for the purpose of home instruction.

TENNESSEE

State Board Election.—At a called meeting of the State Board of Health, May 1, Dr. Thomas E. Abernathy, Chattanooga, was elected president to fill the vacancy caused by the resignation of Dr. Heber Jones, Memphis, who had been a member of the State Health Department for 23 years. Dr. Louis Leroy, Memphis, was elected vice-president; Dr. William Litterer, Nashville, state bacteriologist; Dr. Olin West, Nashville, assistant secretary of the board in charge of the eradication of the hookworm disease, and Dr. Rufus E. Fort, Nashville, delegate to the American Medical Association.

Colleges Close Session.—The graduating exercises of the Medical Department of Vanderbilt University were held May 2, when a class of thirty-nine received diplomas from Chancellor J. H. Kirkland. The faculty address was delivered by Dr. William Litterer.——The University of Nashville Tennessee Medical Department held its annual commencement exercises May 2, when a class of sixty-five was graduated. Ex-Governor R. M. Cunningham, Alabama, delivered the annual address; Dr. Hazel Padgett, the faculty address, and President Brown Ayres of the University of Tennessee outlined the reasons prompting the combination of the two universities and its purpose for the future. Degrees were conferred by Prof. J. I. D. Hines on the graduates of the University of Nashville, and by Prof. Brown Ayres on the University of Tennessee.——The commencement exercises of the Medical School of the University of Chattanooga were held May 2, when a class of eighteen was graduated. The faculty address was delivered by Dr. J. S. B. Woolford. Hon. H. H. Ingersoll, Knoxville, delivered the commencement address, and Professor Race conferred the degrees.——Memphis Hospital Medical College graduated a class of 101, April 30. The commencement address was delivered by Hon. Earl Brewer of Clarksdale, Miss., Hon. W. H. Carroll, president of the board of directors, conferred the degrees, and Dr. William B. Rogers, dean of the college, delivered the diplomas to the graduates.——The College of Physicians and Surgeons, Memphis, held its annual graduating exercises May 2. Prof. Thomas P. Bailey delivered the commencement address, and degrees were conferred on a class of seventeen by Dr. Richard B. Maury, chancellor of the university.——A class of twenty was graduated from the Lincoln Memorial Medical College, Knoxville, May 4. Rev. J. F. Spence, LL.D., vice-president of the Medical Department, conferred the degrees.——Meharry Medical College, Nashville, graduated a class of fifty-five on April 14. The address to the graduates was delivered by Rev. R. E. Jones, D.D., New Orleans. Ground was broken for the George W. Hubbard Hospital, April 13. One wing of this structure is to be built at present, will accommodate about forty patients, and will cost about $15,000.

TEXAS

Personal.—Drs. Edwin P. Beeton, Will Cantrell, Charles T. Kennedy, Julius A. Smith, D. Richard Waddle and John W. Swindell have been elected members of the board of health of Greenville.——Dr. Gustave A. Weidemyer has been elected city physician of Taylor.

Graduation Exercises.—A class of twenty-eight received diplomas at the annual commencement exercises of the Medical Department of Fort Worth University, May 3. Dr. Charles W. Stiles, United States Public Health and Marine-Hospital Service, delivered the commencement address.——Baylor University, Dallas, held its commencement exercises April 26, graduating a class of ten. Dr. Edward H. Carey presented the medical class to President Brooks, who conferred the degrees.

State Physicians Meet.—The forty-second annual meeting of the State Medical Association of Texas was held in Dallas, May 10-12, under the presidency of Dr. Witten B. Russ, San Antonio, and the following officers were elected: President, Dr. John T. Moore, Houston; vice-presidents, Drs. Allen D. McReynolds, Stamford, and Washington A. Harper, Austin; secretary and editor of the state medical journal, Dr. Holman Taylor, *Fort Worth; treasurer*, Dr. Charles A. Smith, Tex*arkana; councilors*. Third District, Dr. David R. Fly, Amarillo; Fifth District, Dr. William A. King, San Antonio; Sixth District, Dr. Henry J. Hamilton, Laredo; Ninth District, Dr. James A. Hill, Houston; Twelfth District, Dr. Arthur C. Scott, Temple; Fifteenth District, Dr. Levi Y. Turner, Daingerfield; and delegates to the American Medical Association, Drs. Witten B. Russ, San Antonio, and Turner, Dallas. The association adopted resolutions favoring the Owen bill to create a national department of health.

VIRGINIA

Commencement.—The Medical College of Virginia held its annual commencement exercises at the Academy of Medicine, Richmond, May 18. President Lyon C. Tyler of William and Mary College delivered the commencement address. A class of forty-six was graduated.

Personal.—Dr. Alick T. Smith has succeeded Dr. Thomas G. Pretlow as city physician of Richmond.——Dr. Albert S. Priddy, formerly superintendent of the Southwestern State Hospital for the Insane, Marion, has been placed in charge of the construction of the state epileptic hospital, Lynchburg, for which an appropriation of $60,000 was made by the last legislature.——Dr. George E. Wiley has succeeded Dr. William R. Rogers, resigned, as city physician of Bristol.——Dr. James C. Bardin, Charlottesville, has accepted the chair of Portuguese in the department of romance languages in the University of Virginia. He will sail for Brazil June 5.

WASHINGTON

Antituberculosis League Formed.—Whatcom County Antituberculosis League was organized at Bellingham, April 28. Dr. Edward C. Ruge was elected president, and Drs. Orville E. Beebe, Everson, and Spencer S. Howe, Lynden, were elected directors.

Personal.—Dr. Charles L. Dixon has been appointed health officer of Renton.——Dr. Grant Calhoun has been appointed chief of the surgical staff, and Dr. Samuel J. Holmes chief of the medical staff of the Seattle City Hospital.——Dr. Elmer M. Brown has been appointed health commissioner of Tacoma.

Building for Antituberculosis League.—A building is to be erected by Mr. Horace C. Henry, Seattle, recently elected president of King County Antituberculosis League, for the use of the organization. The building will contain a reception room, retiring rooms, an office and general committee rooms. Mr.

Dr. Robert Field Library

Henry has also given forty acres of land north of Seattle for a site for a sanatorium, and has made an unconditional promise to build a sanatorium on this site at an expense of from $25,000 to $30,000.

WEST VIRGINIA

Medical Society Library.—The Ohio County Medical Society, Wheeling, has removed its medical library from the city hospital to its leased rooms on the sixth floor of the new Board of Trade Building.

Will Build Sanatorium.—The Ohio County Antituberculosis League, at a meeting recently held in Wheeling, decided to erect a sanatorium to be known as the Hospital for Curable Tuberculosis. The institution will be incorporated with a capital of $50,000. Decision as to the site has not yet been made.

Society Election.—Monongahela County Medical Society, at its annual meeting, held in Morgantown, April 12, elected Dr. Richard H. Edmondson, president; Dr. John N. Simpson, vice-president; Dr. Francisco T. Haught, secretary; Dr. William C. Moser, treasurer, and Dr. Robert W. Fisher, delegate to the state association, all of Morgantown.

WISCONSIN

New Health Commissioner for Milwaukee.—Dr. William Colby Rucker, of the United States Public Health and Marine-Hospital Service, has been granted a leave of absence for one year to accept the position of health commissioner of Milwaukee.

Personal.—Dr. William H. Brown, Madison, has been made assistant professor of pathology in the University of Wisconsin, Madison, and Dr. W. J. Week, assistant professor of physiology.——Dr. George E. Thompson has succeeded Dr. F. B. Lansdowne as city physician of Kenosha.——The Madison General Hospital has appointed a medical staff with three divisions. The medical division is in charge of Dr. Louis R. Head; the surgical division is in charge of Dr. Reginald H. Jackson, and the laboratory division in charge of Dr. Charles H. Bunting.——Drs. George W. Nott and Frank W. Pope have declined to serve as members of the Racine Board of Health.——Dr. J. B. Richards has been appointed health officer of Janesville.——At the annual election of the Kappa Chapter of the Alpha Kappa Kappa Medical Fraternity in Milwaukee recently, Dr. Daniel Hopkinson was elected primarius, and Dr. Fred C. Leifert, corresponding secretary.

GENERAL NEWS AND COMMENT

Meeting of Climatologists.—At the twenty-seventh annual meeting of the American Climatological Association, held in Washington, May 3-5, the following officers were elected: Dr. John Winters Brannan, New York City, president; Drs. Will Howard Swan, Colorado Springs, and John H. Lowman, Cleveland, vice-presidents; and Dr. Guy Hinsdale, Hot Springs, Va., secretary-treasurer. The next meeting will be held in Montreal in June, 1911.

Instructors in Children's Diseases to Meet.—The fourth annual meeting of the Association of Teachers of Diseases of Children will be held at the Southern Hotel, St. Louis, June 6, under the presidency of Dr. Alfred C. Cotton, Chicago. The morning session will be devoted to business, the reports of committees, and a symposium on the teaching of pediatrics. At the afternoon session, a discussion of the papers read at the symposium will take place and papers will be read, and interesting cases will be presented by the St. Louis members of the association.

Medical Museum Directors Meeting.—At the annual meeting of the International Association of Medical Museums, held in Washington, May 3 and 4, the following officers were elected: President, Dr. Alfred S. Warthin, University of Michigan, Ann Arbor; vice-presidents, Prof. G. Sims Woodhead, Cambridge, Eng.; Dr. Edmond Souchon, New Orleans, and Prof. Ludvig Aschoff, Freiburg, Germany; secretary-treasurer, Dr. Maude E. Abbott, McGill University, Montreal; assistant secretary, Dr. H. W. Francis, McGill University, Montreal; and councilors, Drs. William G. MacCallum, Columbia University, New York City; Edwin R. LeCount, University of Chicago; Frank F. Wesbrook, University of Minnesota, Minneapolis; Daniel S. Lamb, Army Medical Museum, Washington; O. S. Woolley, University of Cincinnati; William Ophuls, San Francisco, and George H. Whipple, Baltimore.

Experts in Tropical Medicine to Meet.—The American Society of Tropical Medicine will hold its seventh annual meeting at the Medical School of St. Louis University, June 11, under the presidency of Col. William C. Gorgas, Medical Corps U. S. Army, Ancon, C. Z. The general discussion of hemoglobinuric fever will be opened by Dr. Allen J. Smith, Philadelphia, after the reading of papers by Drs. Charles F. Craig, Washington; George H. Whipple, Baltimore; William H. Deadrick, Helena, Ark.; Walter Brem, Cristobal, C. Z., and James Ewing, New York City. Among other interesting topics for papers and discussions will be filariasis, elephantiasis, uncinariasis, intestinal amebiasis, hookworm, and pellagra.

Adulterated Macaroni Seized and Condemned.—After a trial in the United States District Court at Chicago before Judge Landis May 16, five car-loads of macaroni manufactured by Chicago and St. Louis firms, which had been seized on account of adulteration under the Food and Drugs Act, were condemned and ordered destroyed. The testimony of the government expert chemists, including Dr. H. W. Wiley, showed that the macaroni had been colored by a coal tar dye known as Martius yellow, made by the action of nitric acid on [illegible] and which has been pronounced poisonous [illegible] ities. Prof. Albert Matthews of the physiologic laboratory of Chicago University, by experiments on frogs, guinea-pigs and dogs with some of the drug obtained from this macaroni. found that it was deadly in small quantities. The defense claimed, but did not attempt to show by witnesses, that the dye was purchased from a firm who guaranteed to them that it was not poisonous and that it was one of the coloring matters permitted by the regulations of the Department of Agriculture.

The Gnat the Conveyor of Pellagra?—A press dispatch from London reports that Dr. Sambon announces from Rome that pellagra has been found to be caused by the bite of a species of midge or black fly and that it thus falls into the class of tropical or semitropical diseases of insect conveyance. Dr. L. W. Sambon, lecturer at the London School of Tropical Diseases and the Royal Institute of Public Health, London, is at present a member of the field committee investigating pellagra in Italy. If this announcement is verified it affords a possible explanation of the sudden occurrence of pellagra in this country, or at least its more general recognition in recent years. It has been a puzzle to some American alienists why they did not see such cases before. Some of them at least were more or less familiar with the disease from descriptions in Italian and other foreign literature and must have been on the lookout for it in the asylum population of the corn-raising districts. The assumption has been made by some students of the recent outbreaks that cases have existed unrecognized for a number of years in such parts of the country. This may be true but it is hard to see how so marked a disorder could have passed unnoticed, at least in its typical form. for any length of time. Dr. Sambon's announcement opens up a new lead for American investigators of the subject.

New Medical Buildings at the University of Minnesota.—It is reported that work has already been started at the University of Minnesota toward the erection on the new extension of the university campus of certain buildings which will constitute the new medical group. The buildings for which funds are available are the Elliott Hospital, Millard Hall and the Institute of Anatomy. The construction of the hospital has been already begun and it is expected that work on the other two buildings will follow within the next few weeks. The hospital will provide for 130 free beds, which will be available solely for patients from all over the state without financial resources. All the clinical material will be used for teaching purposes. The building will be of strictly modern construction and will cost $165,000, exclusive of equipment. Of this sum, $125,000 came from Mr. Walter J. Trask through a bequest from the late Dr. A. F. Elliott and $40,000 was appropriated by the last state legislature. Each of the other buildings is planned ultimately to cost $400,000, but only half of each will be completed at this time. The new Millard Hall will be occupied by the offices of the dean and secretary of the faculty, by record, faculty and committee rooms, and by the several laboratories and offices of the departments of medicine, surgery, obstetrics, physiology and pharmacology. The Institute of Anatomy will contain the laboratories of anatomy, histology and embryology and provide also for laboratories in operative and experimental surgery and surgical anatomy. These buildings will not only provide a hospital and the much needed larger quarters for the college of medicine, but they will constitute the begininning of a complete and compact group of strictly modern medical buildings. The erection of these new buildings is another step in the remarkable progress made during the past few years in medical education in Minnesota.

Discuss Measures for Epileptics.—The ninth annual meeting of the National Association for the Study of Epileptics was held in Baltimore, May 7. Dr. Arthur P. Herring, Baltimore, discussed the situation in Maryland, showing that a very large class of epileptics existed for whom under present conditions no adequate provision was made, and advocating special institutions for epileptics. Mr. Franklin Kirkbride, New York City, told about Letchworth Village now the new institution at West Haverstraw. The scope of the institution appears to be rather for the lower mental grades and feeble-minded rather than for the better class of epileptics. Reports from the various state institutions showed that Ohio had 1,412 in its state institution; New York, 1,339; Massachusetts, 900; Kansas, about 400; Texas, 375; New Jersey, 312; Pennsylvania, 138; Missouri, 108; and Indiana about 100. Connecticut and Virginia have established epileptic colonies, and in a few other states there are divisions in other institutions especially for epileptic classes. The president's address was on "The Utility of Organization." He urged that the efforts of the association should be to unite lofty ideals, common sense, well-directed energy, and well-organized effort, as these are the essentials to bring fruition. The following officers were elected: President, Dr. Middleton M. Perry, Parsons, Kan.; vice-presidents, Dr. William T. Shanahan, Sonyea, N. Y., and Charles H. Grasty, Baltimore; secretary-treasurer, Dr. James F. Munson, Sonyea, N. Y.; and editor of the transactions, Dr. William P. Spratling, Baltimore. On all sides, the necessity of more careful study of individual epilepsy was advocated. The time has passed when an individual who has "fits" is called at once an epileptic, and is consigned to the incurable class. It was emphasized that a most careful study of every case, by every method and from every standpoint is necessary since it is becoming more clearly understood that we have to deal not with "epilepsy" but with "epilepsies." Diverse factors in the individual cases must be discovered.

LONDON LETTER

(From Our Regular Correspondent)

LONDON, April 30, 1910.

Prevalence of Adenoids

Adenoids are exceedingly prevalent in the children of Great Britain and their interference with education constitutes a problem in the schools. Mr. Macleod Yearsley of the Royal Ear Hospital has concluded an investigation into the occurrence of adenoids in three of the London elementary schools. He finds that about 37 per cent. of the children have adenoids and that between 72 and 76 per cent. of these have also enlarged tonsils. On an average 31.2 per cent. of these children are mouth-breathers, complete or partial, but hypertrophy of the faucial tonsils may give rise to mouth breathing in the absence of adenoids. Sex appears to have no influence on the incidence of adenoids, and they are most common about the age of 8 and next about the age of 12. True aprosexia occurs in about 4.7 per cent. of adenoid cases and is more frequent in girls and is associated with a marked degree of adenoids. Aprosexia is often confounded with dulness due to defective hearing. The so-called adenoid facies is uncommon except in association with a marked degree of adenoids. The association of an abnormally high palate with adenoids is rather due to peculiarities of cranial formation than to extrauterine influences of nasal stenosis, and if there is any relation between a high, narrow palate and adenoids it is possible that the palate shape is rather a cause of adenoids than *vice versa*. The presence of adenoids has more to do with the presence of carious teeth than have mouth-breathing and palate shape, and this is probably due to the increased tendency to oral sepsis in children with adenoids. Irregularity of the upper incisors is less a result of adenoids than palate shape. The percentage of ear complications in adenoid children is about 10.8 and adenoids are probably by far the most important factor in the etiology of ear diseases in childhood.

Scotland's Low Birth-Rate

The low birth-rate of England has from time to time been a subject in previous letters to THE JOURNAL. The fifty-fifth annual report on births, deaths and marriages in Scotland shows that a similar decline has taken place in that country. For 1909, the birth-rate is 26.3 per thousand, the marriage-rate 6.17, and the death-rate 15.2. All these rates are the lowest recorded in the 55 years covered by the registrar-general's returns. The marriage-rate is 0.14 less than the previous lowest record which occurred in 1886. The death-rate is 0.64 less than that of 1905, previously the lowest recorded. The Vaccination Act of 1907, which made a conscientious objection of parents to vaccination a valid excuse for non-vaccination is producing similar evil effect to that in England (previously described in THE JOURNAL). The number of children unvaccinated is now 20,000 more than before the passing of the act.

Plague in India

The Indian plague returns for the week ending March 19 show a great increase of the number of cases in mortality in the Punjab in which the number is 10,787. The number for the whole of India is 27,642. The incidence of the disease from year to year varies in a very irregular fashion. Thus in 1905 the number of deaths was 126,000; in 1906 the number dropped to less than half of this; but in 1907 it again rose to 83,600. In 1908-09 the disease died down except in few localities and the number of deaths was less than 16,000. Inoculation against plague is still regarded with great distrust by the natives and not more than 5,000 or 6,000 submit themselves annually to prophylactic inoculation.

Hospital Bed Endowed by the Emperor of Japan

At the Seamen's Hospital, Greenwich, the Japanese ambassador unveiled a tablet over a bed which had been endowed by the Emperor of Japan. He expressed the emperor's gratitude that such an institution as the Seamen's Hospital existed where so much care and attention were bestowed on Japanese seamen admitted to its wards.

PARIS LETTER

(From Our Regular Correspondent)

PARIS, May 6, 1910.

Conference for the Welfare of the Blind

A conference for the welfare of the blind, organized by the cooperation of the Syndicat général des oculistes français, the Institution nationale des jeunes aveugles, the Hospice national des Quinze-Vingts, the Association Valentin-Haüy, etc., has just been held in Paris. M. Mirman, director of the public charities and hygiene, presented to the conference a report on the law of 1905 and relief for the blind. He proposed certain resolutions demanding especially that a campaign of propaganda be undertaken by means of circulars, pamphlets and the public press, to induce the municipal councils to grant assistance to every young blind person who is capable of being professionally educated—this assistance not to take the form of a monthly allowance, but of maintenance at a special professional school, or, in default of such school, with a person who should undertake to teach a trade to the blind pupil; that in each important center private initiative should found a residential institution, where in exchange for an amount equal to the monthly allowance which the blind receive in accordance with the law of 1905, blind persons capable of working or those whose wives and daughters are compelled to work outside, might be lodged and cared for under good hygienic conditions. Dr. Valude, physician of the ophthalmologic clinic of the Hospice des Quinze-Vingts, took up the especially interesting question of blindness caused by ophthalmia neonatorum and the means of combating it. He spoke of the circular that M. Clemenceau addressed last year to the prefects on this subject (THE JOURNAL, May 22, 1909, lii, 1676). Dr. Valude advocates making the Credé method of using nitrate of silver immediately after the birth of a child, an important compulsory part in the instruction of midwives. He also recommends that midwives be obliged, under penalty, not only to declare confirmed ophthalmia, but to have it immediately cared for by a physician; and that the public be informed of the dangers of ophthalmia by concise information distributed to parents, by notices posted up in the mayors' offices and in schools, by lectures given in neighborhoods where working people live; and that medical students be compelled to pass examinations on the elementary questions of ophthalmology.

Zambaco Pasha Prize

Dr. Zambaco Pasha of Constantinople, associate member of the Académie de Médecine and corresponding member of the Académie des Sciences, has just endowed the Société de médecine et d'hygiène tropicales with three prizes, one of $200 (1,000 francs) and two of $100 (500 francs) for the three best memoirs on the question of the contagiousness of leprosy. The works are to be the result of personal research and of scientific observations made at first hand. The commission which is to award the prizes has just decided that the candidates shall discuss the following questions: 1. Is leprosy hereditary? 2. Is leprosy contagious among human beings? 3. Is leprosy transmissible to animals? If there is occasion, means of control, such as microscopic preparations and photographs, should be appended to the memoirs. The papers should be written in French, should be addressed to the Secrétaire général de la société de médecine et d'hygiène tropicales at 18 rue de Grenelle, Paris, and should reach him before April 1, 1911.

Franco-Belgian Convention for the Declaration of Epidemic Diseases

The French and Belgian governments, by a series of agreements concluded since 1895, the last of which was signed recently, have decided on reciprocal notification of epidemic diseases by the authorities in the frontier zones. The diseases which affect human beings which are to be reported in these regions are Asiatic cholera, bubonic plague, typhus, typhoid fever, smallpox, scarlatina, diphtheria, measles, dysentery, contagious ophthalmia, puerperal fever, cerebrospinal meningitis and all epidemic and transmissible diseases. The diseases affecting animals which are to be reported are contagious typhus, contagious pleuropneumonia, aphthous stomatitis, glanders, farcy, sheep-rot, scabies and swine plague. Notification is to be given on the appearance of the first cases, whether confirmed or suspected.

BERLIN LETTER

(From Our Regular Correspondent)

Berlin, April 28, 1910.

Bill to Regulate Compulsory Insurance

The bill modifying the present legislation on compulsory insurance of wage-earners is having its first reading in the Reichstag (every bill must be considered three times in the parliament). It appears that the various parties are more favorable to the wishes of the medical profession than was to be expected. The repeated communications of physicians have plainly not been without effect on the legislators, and especially influential in this line was the extraordinary meeting of the medical association, the Aerztetag, April 17 in Berlin, at which about 24,000 physicians were represented by delegates. With a few exceptions the delegates were unanimous in the opinion that the new bill, in spite of some important improvements, is not calculated to secure the harmony in the Krankenkassen relations which is desirable in the interests of the social legislation and the economic interests of the medical profession, and that the demands voted at the regular Aerztetag, at Lübeck, must be maintained. Especially the free choice of physician must be legally guaranteed. In fact, at the recent discussions in the Reichstag, a representative of the social democratic party announced himself as an adherent to the principle of the free choice of physician, and thus it is to be hoped that this party, which includes the principal opponents in the Krankenkassen to the demands of the medical profession, will vote favorably to these demands. The government has indeed made provision for the management of the medical affairs of the Krankenkassen in both ways, by the so-called fixed physicians and by free choice. However, it will without doubt yield if the Reichstag votes differently. Possibly the government was favorably influenced by the petition presented by the medical faculties of practically all the German universities on the suggestion of the editor of the *Deutsche medizinische Wochenschrift*. In this petition 150 professors supported the demands of the practitioners for the improvement of the imperial insurance law and distinctly called attention to the dangers which threaten the independence of the medical profession if the bill in its present form shall be enacted into law.

Centennial of the Berlin Medical University Policlinic

On May 2 our university policlinic for internal medicine will celebrate its centennial. It was founded by Hufeland, who delivered the first lecture in it. His successor in 1833 was his son-in-law, Professor Osann, who was a teacher of pharmacology in the university. Then followed, in 1842, the renowned neurologist, Professor Romberg (the discoverer of the so-called Romberg sign in tabes). He was followed, in 1865, by the distinguished psychiatrist, Professor Greisinger, who continued in office only two years because he was too much in demand at the newly-founded clinic for mental and nervous diseases at the Charité. Prof. J. Mayer, who was not distinguished in science but a good practitioner and teacher, succeeded him. After the death of Mayer, in 1887, Professor Senator became the director of the institute, and has retained this post for twenty-three years, but resigns now with the end of the summer semester. Although in the early years on the average only 700 patients were treated in the policlinic, their number of late years has risen to 10,000. In the beginning the patients were treated not only in the clinic but also by assistants and students in their own homes, but for a number of years this part of the policlinic work, so important for instruction, has been discontinued on account of lack of room. The number of students attending the policlinic is still relatively large, as Professor Senator, in spite of his advanced age, shows still a remarkable activity in teaching. No decision has been made as to his successor.

Pharmacology

[Contributions from the Chemical Laboratory of the American Medical Association.]

NOITOL AND ANADOL

W. A. Puckner and L. E. Warren

NOITOL

The Journal received an inquiry concerning the composition of Noitol, a preparation which is being advertised to the medical profession as a "specific" for the cure of eczema and certain other cutaneous diseases. The preparation is manufactured by the Wheeler Chemical Works, Chicago. Trade packages of Noitol were purchased and examined in the Association laboratory. On the label of the package, Noitol—an inversion of the word "lotion"—is described as follows:

> NOITOL
> (Dr. Bradbury's Eczema Lotion.)
> For External Application Only!
> Our Most Popular Specialty.
>
> A specific for the cure of Eczema, Scrofulous and Syphilitic Eruptions, Lupus, Salt Rheum, Tetter, Itch. This remedy is composed of valuable Oils, combined with Vegetable and Mineral Acids in such proportions as cause a rapid and permanent cure of the above complaints.

Noitol is a clear, nearly colorless, acid solution, the greater portion of which is water. Its specific gravity is 1.0097 at 25 C.

Qualitative tests demonstrated the presence of a chlorid, a nitrate, a mercuric salt, free acid and glycerin. No "oils" or "vegetable acids" could be found.

The analysis[1] of the preparation indicated that its composition is essentially as follows:

Mercuric Chlorid	0.0463 gm. in 100 c.c.
Mercuric Nitrate	0.0450 gm. in 100 c.c.
Glycerin	1.3021 gm. in 100 c.c.
Nitric Acid	1.0265 gm. in 100 c.c.
Water (by difference.)...........	98.5545 gm. in 100 c.c.

From the above it appears that Noitol is simply a weak, acid solution of mercury salts—the total being approximately equivalent to a 1 to 1,000 bichlorid of mercury solution—exploited under a meaningless name. It is but one more example of the old, old story of a well-known remedy being sold at a high price under a name which is in no way indicative of its composition, and under claims which are absurdly false.

The price of the mixture is $2.00 a pint; the estimated cost, exclusive of the container, is about 6 cents a gallon, or, put another way: the price of a pint bottle, it is estimated, would make a barrel (31 gallons) of the nostrum. The incorrect statement made concerning its components, the unwarranted therapeutic claims made for it, and the exorbitant price easily place Noitol in the front rank among the "patent medicine" frauds. *Yet it is advertised to physicians as an ethical proprietary* and is evidently being prescribed by them.

ANADOL

In the circular matter accompanying the trade package of the preparation, "Noitol," described above, a preparation called "Anadol" is described. Anadol is claimed to be an analgesic and antipyretic. In the descriptive circular there is no information concerning the composition of the preparation but from the general therapeutic description the physician might easily be led to believe that "Anadol" is a distinct chemical substance.

To reduce temperature the physician is advised to push the administration of Anadol in 10 grain doses until the febrile condition is under control or until a maximum of 70 grains of the preparation has been ingested. The circular further states:

> ". . . in this lies the special value of ANADOL; there are no annoying by-effects; the stomach bears the remedy well and neither circulation, respiration, nor the nerve centers show the least disturbance."

---

[1] The details of the analysis will be sent on receipt of a stamped, addressed envelope; they will also be published in the annual report of the Chemical Laboratory.

As no evidence could be obtained concerning the composition of Anadol and, as the preparation is being brought to the attention of physicians by means of circulars in connection with the distribution of Noitol, it seemed worth while to take up its examination in the Association laboratory. Accordingly a trade package of the material which had passed into interstate commerce was purchased.

Qualitative tests demonstrated the presence of sodium, a carbonate, caffein and acetanilid, the latter in considerable quantities. Analysis[2] indicated that the composition of the specimen examined is essentially as follows:

Acetanilid	79 per cent.
Caffein	1 per cent.
Sodium bicarbonate	20 per cent.

Since, according to the circular, it is permissible to prescribe 70 grains of this preparation within 2½ hours, a patient thus treated would receive no less than 55 grains of acetanilid! In view of the numerous cases of poisoning due to the misuse of acetanilid ("The Harmful Effects of Acetanilid, Antipyrin and Phenacetin," U. S. Dept. Agric., Bur. Chem., Bull. No. 126) the physician should be apprised of the composition of Anadol.

Editorial Note: The chemical investigations reported above emphasize once more the need of such an institution as the Association's laboratory and again demonstrate the value of its work. At first sight it seems disheartening to find that physicians are so easily humbugged. Yet when it is remembered that it is impracticable for physicians either to analyze such products themselves or to go to the expense of having chemists do it for them, it is evident that the fault lies not so much with the physician as with the conditions that makes the exploitations of such frauds possible. It is on the public that the burden ultimately falls, for it is the layman who has to pay two dollars for a few cents worth of medicine. But—and this is far more serious—that the physician should be urged to dose his patient with an insidiously dangerous drug to a point far beyond the limits of safety, is little less than criminal. Yet so long as unknown medicinal products are prescribed just so long will this danger be a very real one.

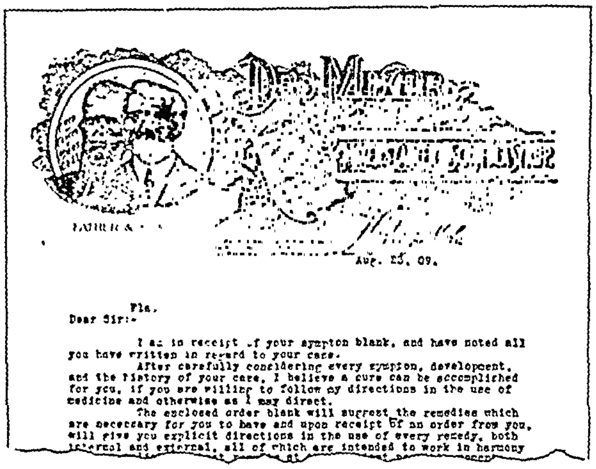
DRS. MIXER

Another Cancer Cure Concern Declared Fraudulent by the Postoffice Authorities

[The postal authorities have done the public great service during the past year or two in declaring fraudulent and denying the use of the United States mails to a number of "cancer cure" concerns. The facts brought out by the federal investigations have appeared in abstract form in the pages of The Journal and more complete accounts have been published as pamphlets. The following case is one of the latest in which a fraud-order was issued. It will appear in more extended form as a pamphlet.]

Drs. Mixer was the name under which C. W. Mixer of Hastings, Mich., conducted a mail-order "cancer cure" concern. There were no Drs. Mixer, C. W. Mixer being neither a graduate in medicine nor licensed to practice medicine. His methods differed but little from those of similar concerns. About the only variation from the stereotyped claims and ways of the "cancer cure" fraternity was in the representation that C. W. Mixer's father (who, by the way, had been dead many years) had a cancer that the "best physicians in America" could not cure. He—Mixer, senior—then "discovered the great remedy that cured him," and, of course, the same "remedy" was the one now sold by Drs. Mixer.

In other respects the methods of this concern did not differ from those of the other "cancer cure" frauds which have been exposed. The claims were equally extravagant and the system of follow-up letters in no wise original. The "remedy" was claimed to have cured 86 per cent. of those who had taken it and equal success was said to have attended the treatment of either internal or external cancer. The usual symptom blank was to be filled out by the victim and on payment of the required fee a batch of medicines would be sent.



Aug. 23, 09.

Fla.
Dear Sir:-

I am in receipt of your symptom blank, and have noted all you have written in regard to your case.

After carefully considering every symptom, development, and the history of your case, I believe a cure can be accomplished for you, if you are willing to follow my directions in the use of medicine and otherwise as I may direct.

The enclosed order blank will suggest the remedies which are necessary for you to have and upon receipt of an order from you, will give you explicit directions in the use of every remedy, both internal and external, all of which are intended to work in harmony

Photographic reproduction of part of the circular letter which the victims received after sending in the "symptom blank."

Dr. F. P. Morgan of the Department of Agriculture opened correspondence with Drs. Mixer under an assumed name and on filling out a symptom blank he was told that the case described was one of cancer. Mixer perceived "no reason why you can not be cured" and on the receipt of $11.80 sent the "treatment" which consisted of seven medicines. These nostrums were analyzed in the government laboratories and were found to be composed, respectively, as follows:

1. "Mixer's Cancer and Scrofula Syrup": A syrup containing potassium iodid, 6 per cent., alcohol and a small amount of vegetable ingredient similar to sarsaparilla flavored with methyl salicylate.
2. "No. 1 Wash": Solution of hydrogen peroxid.
3. "No. 1 Alterative": A mixture of alcohol and water containing a large amount of glycerin and a small amount of what appeared to be gentian.
4. "Cancer Reducer": A strong alcoholic solution of camphoraceous oils, with considerable glycerin.
5. "Cancer Paste": Vaselin (petrolatum) containing a large amount of ground flaxseed and some camphoraceous substance with what appeared to be hyoscyamus.
6. "Cancer Salve": A mixture of vaselin (petrolatum) and lanolin (wool-fat) with powdered opium and tannin.
7. "Cleansoine Soap Powder": Powdered soap containing borax and thymol.

In the advertising matter sent out by Mixer every effort was made to impress prospective victims with the idea that the concern was conducted by physicians. Nor was this the only element of fraud. Part of the "literature" contained a reprint of an article entitled "Palliatives and Curatives in the Treatment of Cancer and Scrofula," by C. H. Brown, M.D., from the *American Journal of Health.* This was prefaced with the statement: "The following is reprinted from one of the leading journals of the country." As a matter of fact, the *American Journal of Health* was not a "leadindg journal" but a fraudulent publication, printed to sell laudatory notices to mail-order medical concerns. These concerns then used such notices as being the indorsement of a medical publication. At the hearing Mixer admitted that he paid five or ten dollars—he could not recall the exact amount—for the article.

The usual defense was offered—testimonials. There was no satisfactory evidence adduced to show that the individuals claiming to have been cured of cancer by the Drs. Mixer treatment ever had cancer. As the assistant attorney-general said in recommending that a fraud-order be issued: "It is to be expected that out of the multitude of cases that this advertiser treats each year there should be a certain number of instances in which persons do not have cancer at all but are afflicted with some non-malignant sores which are amenable to treatment [Especially to treatment with potassium iodid, which Mixer used!—ED.] and which in some instances do yield to treatment." After hearing all the evidence against Mixer as well as the defence offered by his attorney, together with some remarks in behalf of the "cancer curer" by the congressman from his district—E. L. Hamilton—the assistant attorney general reported: "I find that this is a scheme for obtaining money through the mails by means of false and fraudulent pretenses, representations and promises, and I therefore recommend that a fraud order be issued against Drs. Mixer." And it was issued.

---

[2] The details of the analyses will be sent on receipt of a stamped self-addressed envelope.

REPORT OF PHARMACOPEIAL CONVENTION

Held in Washington, D. C., May 10-13, 1910

While the medical profession was not so well represented at this convention as it should have been, nevertheless there were more medical men in attendance than at the last convention. As is well known, the main business of the convention is to provide for the revision of the Pharmacopeia and the principal part of this is the election of the revision committee. Heretofore, the revision committee has consisted of twenty-five, but this number was considered too large for practical work and too small to be representative. A radical change was made in that the committee of revision was enlarged to fifty; this large committee selects from its number fifteen who are to be known as the executive revision committee. While the whole committee of fifty has general supervisory functions the smaller committee will be responsible for the work.

It will be noted that the medical men on the revision committee are in an extreme minority, only three or four practicing physicians being in the list. While this is true, the medical profession is much better represented than heretofore for the reason that a considerable number of the revision committee represent medical interests and the medical profession. The Council on Pharmacy and Chemistry is well represented, having eight of its members on the committee of revision.

Officers Elected

A decided compliment was paid Dr. H. W. Wiley by the convention when it selected him as its president. The following officers were elected: President, Dr. H. W. Wiley, Washington, D. C.; first vice-president, Dr. N. S. Davis, Chicago; second vice-president, Prof. Charles Caspari, Jr., Baltimore; third vice-president, Dr. Oliver T. Osborne, New Haven, Conn.; fourth vice-president, Mr. Leo Eliel, South Bend, Ind.; fifth vice-president, Dr. W. A. Bastedo, New York; secretary, Dr. M. G. Motter, Washington, D. C.; assistant secretary, Dr. Noble P. Barnes, Washington, D. C.; treasurer, Mr. S. L. Hilton, Washington, D. C.

GENERAL COMMITTEE OF REVISION

Alpers, William C., Retail Druggist, New York.
Anderson, John F., Director, Hygienic Laboratory, United States Public Health and Marine-Hospital Service.
Arny, Harry V., Professor of Theory and Practice of Pharmacy, Cleveland School of Pharmacy.
Bartley, Elias H., Professor of Chemistry, Toxicology and Pediatrics, Long Island College Hospital, Brooklyn, N. Y.
Beringer, George M., Retail Druggist, Camden, N. J.
Bodemann, Wilhelm, Retail Druggist, Chicago.
Caspari, Charles, Jr., Professor of Theory and Practice of Pharmacy, University of Maryland, Department of Pharmacy.
Caspari, Charles E., Professor of Chemistry, St. Louis College of Pharmacy.
Coblentz, Virgil, Professor of Chemistry, College of Pharmacy of the City of New York.
Davis, Nathan S., Professor of Principles and Practice of Medicine and Clinical Medicine, Northwestern University Medical School.
Diehl, C. Lewis, Professor of Practical Pharmacy, Louisville College of Pharmacy.
Diekman, George C., Professor of Theory and Practice of Pharmacy, College of Pharmacy of the City of New York.
Dohme, Alfred R. L., Chemist, Sharp & Dohme, Baltimore, Md.
Eberle, Eugene G., Editor, The Southern Pharmaceutical Journal, Dallas, Tex.
Edmunds, Charles Wallis, Professor of Therapeutics and Materia Medica, University of Michigan, Department of Medicine and Surgery.
England, Joseph W., Director Scientific Department, Smith, Kline & French Company, Philadelphia.
Francis, John M., Chemist, Parke, Davis & Company, Detroit.
Good, James M., Professor of Theory and Practice of Pharmacy, St. Louis College of Pharmacy.
Gordin, Harry M., Professor of Chemistry, Northwestern University, Department of Pharmacy.
Gregory, Willis G., Buffalo College of Pharmacy.
Haines, Walter S., Professor of Chemistry, Materia Medica and Toxicology, Rush Medical College, Chicago.
Hallberg, Carl S. N., Professor of Theory and Practice of Pharmacy, University of Illinois, School of Pharmacy.
Hatcher, Robert A., Professor of Pharmacology, Cornell University, Medical Department, New York.
Hopp, Lewis C., Retail Druggist, Cleveland.
Hunt, Reid, Chief, Division of Pharmacology, Hygienic Laboratory, United States Public Health and Marine-Hospital Service.
Kebler, Lyman F., Chief of Drug Laboratory, Bureau of Chemistry, U. S. Department of Agriculture.
Koch, Julius A., Professor of Chemistry, University of Pittsburgh, Department of Pharmacy.
Kraemer, Henry, Professor of Botany and Pharmacognosy, Philadelphia College of Pharmacy.
Kremers, Edward, Professor of Chemistry, University of Wisconsin, School of Pharmacy.
LaWall, Charles H.; Associate Professor of Theory and Practice of Pharmacy, Philadelphia College of Pharmacy.
Long, John H., Professor of Chemistry, Northwestern University Medical School, Chicago.
Lyons, Albert B., Chemist, Nelson, Baker & Company, Detroit.
Marvel, Philip, Physician, Atlantic City, N. J.
Nixon, Charles F., Retail Druggist, Leominster, Mass.
Osborne, Oliver T., Professor of Therapeutics and Materia Medica, Yale Medical School.
Plaut, Albert, Wholesale Druggist (Lehn & Fink), New York.
Puckner, W. A., Director of Chemical Laboratory, American Medical Association, Chicago.
Raubenheimer, Otto, Retail Druggist, Brooklyn, N. Y.
Remington, Joseph P., Professor of Theory and Practice of Pharmacy, Philadelphia College of Pharmacy.
Rosengarten, George D., Chemist, Powers-Weightman-Rosengarten Company, Philadelphia.
Rusby, Henry H., Professor of Botany and Materia Medica, College of Pharmacy of the City of New York.
Sadtler, Samuel P., Professor of Chemistry, Philadelphia College of Pharmacy.
Sayre, Lucius E., Professor of Materia Medica, University of Kansas, School of Pharmacy.
Schlotterbeck, Julius O., Professor of Pharmacognosy and Materia Medica, University of Michigan, School of Pharmacy.
Sollmann, Torald, Professor of Pharmacy and Materia Medica, Western Reserve University Medical Department.
Stevens, A. B., Professor of Theory and Practice of Pharmacy, University of Michigan, School of Pharmacy.
True, Rodney H., Physiologist, Bureau of Plant Industry, U. S. Department of Agriculture.
Vanderkleed, Charles E., Chemist, H. K. Mulford Company, Philadelphia.
Wilbert, M. I., Assistant Pharmacologist, Hygienic Laboratory, United States Public Health and Marine-Hospital Service.
Wood, Horatio C., Jr., Associate Professor of Pharmacology, University of Pennsylvania.

Correspondence

A Medical Play by a Medical Man at a Medical Society Meeting

To the Editor:—Dr. Dan Millikin is not only an honored practitioner, having been president of the Ohio State Medical Society in 1895 and being a descendant of a long line of physicians, himself and son Dr. Mark Millikin representing respectively the fourth and fifth generations practicing in their native city, but he is also a playwright and actor of local and state fame. At the meeting of the Ohio State Medical Society in Toledo, May 11, an audience of 800 physicians and their wives greeted Dr. Millikin and his talented company from Hamilton in a way that left no doubt about the attractiveness of this particular play, and the merits of this style of entertainment of medical men. The medical comedy entitled "What Would Mrs. MacThinkar say?" is brilliant and clever and the players showed talent and excellent training.

But it is not to call attention to this play or to the artists in particular but rather to comment on entertainments that this letter is written. We should break away from the conventional vaudeville and punch affairs and cultivate a line of amusements that have characteristic, and educational qualities. Professional experience is overflowing with material ready for the touch of the playwright, and at the same time, as our experience shows, a medical audience is especially "sensitized" to appreciate the humor and pathos characteristic of a well-presented medical comedy.

THOMAS HUBBARD.

The Public Service

Medical Department, U. S. Army

Changes for the week ended May 14, 1910:

The following named officers of the Medical Corps are detailed as instructors in the subjects specified after their respective names at the school for officers of the Medical Corps of the National Guard of Ohio, to be held in Columbus, Ohio, June 8 and 9, 1910:

Munson, Edward L., major, Camp Sanitation and Medical Organization in the Field.

Reynolds, Charles R., major, Manual, Medical Department, and Field Service Regulations.

Fisher, Henry C., major, Physical Examination of Recruits.

Pipes, Henry F., capt., Papers and Records.

Morgan, Norman D., C. S., reported for duty at Presidio of San Francisco.

Hallett, H. J., 1st lieut., M. R. C., reported for temporary duty at Fort Hamilton, New York.

Pulver, A. L., 1st lieut., M. R. C., reported for temporary duty at Fort Jay, N. Y.

Brownlie, James W., C. S., ordered to proceed from San Francisco, to the Presidio of San Francisco, and report to the commanding officer, detachment of Company M, 3rd Battalion of Engineers, for duty with and to accompany that command to Ataccadero, Cal.

Stephenson, William, lieut. col., ordered to proceed from Fort Leavenworth, Kan., to Fort D. A. Russell, Wyo., for duty with Battery C, 2nd Field Artillery from that post to San Francisco, then return to his station.

Woodall, William P., capt., ordered to Fort D. A. Russell, Wyo., for duty.

Bierbower, H. C., 1st lieut., M. R. C., on expiration of leave of absence ordered to Fort Robinson, Neb., for duty.

Boyer, Perry L., capt., ordered to Fort Mason, Cal., for temporary duty, and for temporary duty as attending surgeon, San Francisco, in addition to his duties at Fort Mason, Cal.

Eastman, William R., capt., on expiration of leave of absence ordered to Fort Mason, Cal., for duty, and attending surgeon at San Francisco.

Keefer, Frank R., lieut. Col., promoted to, with rank from April 14, 1910.

Grubbs, Robert B., major, promoted to, with rank from April 14, 1910.

Ekwurzel, George M., major, on the expiration of his present leave of absence ordered to Fort Mackenzie, Wyo,, for duty.

Brooks, William H., major, ordered to accompany 35th Company Coast Artillery from San Francisco, to Fort Monroe, Va., then return to his proper station.

Delacroix, A. C., 1st lieut., M. R. C., on arrival at San Francisco, ordered to accompany troops to Fort Sill, Okla., on completion of this duty to proceed to Boise Barracks, Idaho, for duty, as heretofore ordered.

Peck, Luke B., 1st lieut., M. R. C., granted leave of absence for 1 month and 10 days.

Miller, Reuben B., capt., granted 15 days' leave of absence.

Mason, D. S., the leave of absence heretofore granted is extended 2 months and 20 days.

Sweazey, Verge E., capt., granted 4 months' leave of absence.

Billingslea, C. C., capt., leave of absence extended 1 month.

Pulver, Arthur L., 1st lieut, M. R. C., relieved from temporary duty at Fort Jay, N. Y., and ordered to Fort Wood, N. Y., for temporary duty.

Little, William L., capt., relieved from temporary duty at Fort Wood, N. Y., and ordered to return to station, Fort Adams, R. I.

Sharpe, Herbert H., 1st lieut., M. R. C., relieved from temporary duty at Fort Adams, R. I., and ordered to return to station, Fort Jay, N. Y.

Tefft, William H., capt., granted leave of absence for 1 month.

Straub, Paul F., major, detailed as a member of the General Staff Corps.

Medical Corps, U. S. Navy

Changes during the week ended May 14, 1910:

Bogan, F. M., surgeon, detached from the *Wisconsin*, and ordered to the *Nebraska*.

Heiner, R. G., P. A. surgeon, detached from the *Independence* and ordered home to wait orders.

Bogan, F. M., surgeon, orders of May 6, detaching from the *Wisconsin* and ordering to the *Nebraska*, revoked.

Cather, D. C., P. A. surgeon, ordered to the Naval Academy.

Kaufman, J. B., asst.-surgeon, ordered to the Navy Yard, Norfolk, Va.

Ely, C. F., P. A. surgeon, detached from the Naval Station, Olongapo, P. I., and ordered to the *Wilmington*.

Higgins, S. L., P. A. surgeon, detached from the *Wilmington* and ordered home.

Higgins, M. E., asst.-surgeon, detached from the *Charleston* and ordered home.

U. S. Public Health and Marine-Hospital Service

Changes for the week ended May 11, 1910:

Carter, H. R., surgeon, granted 5 days' leave of absence from May 29, 1910.

Carmichael, D. A., surgeon, granted 14 days' leave of absence from May 27, 1910:

Cobb, J. O., surgeon, granted 7 days' leave of absence from May 7, 1910.

Wertenbaker, C. P., surgeon, granted 4 days' leave of absence from May 4, 1910.

Goldberger, Joseph, P. A. surgeon, granted 7 days' leave of absence from April 29, 1910, under paragraph 191, Service Regulations. Granted 14 days' leave of absence from May 6, 1910.

Bahrenburg, L. P. H., P. A. surgeon, granted 14 days' leave of absence from April 22, 1910, on account of sickness.

Rucker, W. C., P. A. surgeon, granted 1 month's leave of absence from May 4, 1910.

Warner, H. J., asst.-surgeon, granted 9 days' leave of absence from May 16, 1910.

Ridlon, J. R., asst.-surgeon, directed to report at Bureau for special temporary duty.

Leake, James P., asst.-surgeon, granted 7 days' leave of absence from April 12, 1910, under paragraph 191, Service Regulations.

Hallett, E. B., acting asst.-surgeon, granted 1 day's leave of absence, May 7, 1910.

Lawhorn, C. C., acting asst.-surgeon, granted 13 days' leave of absence from May 11, 1910.

Onuf, B, acting asst.-surgeon, granted 2 days' extension of leave of absence from April 26, 1910, on account of sickness.

Board of medical officers convened to meet at Montreal, Canada, May 3, 1910, for the purpose of e [illegible] Detail for the board: Passed Assistant Surgeo[illegible] man; Acting Asst.-Surgeon George Mathewson; [illegible] Fred Tooke, recorder.

Board of medical officers convened to meet at the Marine Hospital, San Francisco, May 16, 1910, for the purpose of conducting a physical examination of an officer of the U. S. Revenue-Cutter Service. Detail for the board: Surgeon J. M. Gassaway, chairman; Passed Assistant Surgeon R. E. Ebersole, recorder.

Queries and Minor Notes

Anonymous Communications will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

THE LOCAL ANESTHETIC EFFECT OF QUININ: A CLAIM OF PRIORITY

To the Editor:—Allow me to state, in answer to the letter of Dr. W. S. Hoy on this subject (The Journal, May 14, 1910, p. 1628) that my experimental work resulting in the discovery of the local anesthetic effect of quinin was done in 1885, more than ten years prior to my published report in 1896. This, I believe, establishes the matter of priority as far as this is shown by any published claims to date. According to Dr. Hoy's statement, Dr. Sylvester began the use of quinin as a local anesthetic endermically (not hypodermically) about twenty-two years ago.

V. M. Griswold, M.D., Fredonia, N. Y.

TRIPLE KIDNEY

To the Editor:—Please let me know how many cases of triple kidney have been reported, when and by whom, and the location of the third kidney.

E. S. Lauzer, Rock Springs, Wyo.

Answer.—This anomaly is very rare and its existence has been doubted by some authors. The following are all the distinct references to cases that we have been able to find.

Beauchêne fils: Description de trois reins réunis trouvés dans le cadavre d'une jeune femme, *Bull. Fac. de méd. de Paris,* 1810, ii, 30.

Renaud: Des reins réunis par une espèce de bande à la forme d' un troisième rein, *Bull. Soc. anat. de Paris,* 1835, x, 2

Supernumerary Kidney, *London Med. Gaz.*, 1838, new series, ii, 127.

Hyrtl: Ein wahrer Ren tertius, *Oester. med. Wchnschr.*, 1841, p. 995.

Amick: Four Kidneys, *Cincinnati Med. Reports,* 1871, iv, 551-554.

Morris: Rep. Surgeon-General Marine-Hospital Service, U. S. A., 1885, p. 148.

Cheyne, W.: *Lancet,* London, 1899, i, 215.

Rep. Supervising Surgeon Marine Hospital, Washington, 1884-5, pp. 148-150.

Jump, R. L.: Supernumerary Kidneys, *Occidental Med. Times,* 1894, viii, 173.

Von Hansemann: Double Kidney, *Berl. klin. Wchnschr.,* 1897, No. 4.

Barlet, J. M.: A Pathologic Curiosity (Supernumerary Kidney), *Lancet,* London, 1904, i, 124.

Calabrese: Rein supernuméraire constaté pendant la vie, *Ann. d. mal. d. org. génito-urin.,* 1908, ii, 1841.

Calabrese: Encore un rein supernuméraire constaté pendant la vie, *Ann. d. mal. d. org. génito-urin.,* 1909, i, 749.

Desnot and Minet: ("Maladies des voies urinaires," p. 1044) say: This anomaly is exceedingly rare. The supernumerary kidney may be fused with the two others, in which case it has been classed as a trilobate kidney.

H. Kümmel says that supernumerary kidneys occur. Four kidneys were present twice; three were found once ("Ergänzungsbuch des Handbuch der praktischen Medizin," Edition 2, 1907; Ebstein, W., and Schwalbe, J.: Chirurgie des praktischen Arztes, p. 602).

As to the location of the third kidney, we find in Rauber-Kopsch "Lehrbuch der Anatomie," Edition 7, Part 4, The Intestines, p. 211, the statement: "The third kidney lies usually in front of the vertebral column or at one side of it or in the pelvis."

Reference may also be made to Rayer: "Maladies des reins," and to Cadoré, F. L.: "Les anomalies congénitales du rein," published by Masson, Lille, 1903, p. 205.

Marriages

Simon Wendkos, M.D., to Miss Sarah Seidman, both of Philadelphia, May 8.

Julian A. Hielscher, M.D., to Helen Hughes, M.D., both of Mankato, Minn., May 2.

Jacob Myers, M.D., Chicago, to Miss Gertrude Myers, of Mount Pulaski, Ill., April 20.

Hayden Lyle Fischer, M.D., Kewanee, Ill., to Miss Georgia Elizabeth Poole, of Chicago, May 18.

Harlow V. Wilson, M.D., to Mrs. Daisy Jones, both of Champaign, Ill., at Chicago, April 30.

Alva V. McCurry, M.D., Baltimore, Md., to Miss Frances Varina Robertson, at Baltimore, January 3.

John G. Bickley, M.D., to Miss Tina M. Stewart, both of Waterloo, Iowa, at Morrelton, Ark., April 29.

Charles Fisher Andrew, M.D., Longmont, Colo., to Mrs. Sadie Whitney, of Denver, at Chicago, recently.

Lucius Warren Johnson, M.D., U. S. Navy, to Miss Margaret Crosby Cranston, of Washington, D. C., May 17.

Deaths

Howard H. Barker, M.D. Georgetown University, Washington, D. C., 1870; a member of the American Medical Association; formerly president of the American Therapeutic Society, Medical Association of the District of Columbia, and Washington Therapeutic Society; professor of obstetrics and gynecology and dean of the Medical Department of Georgetown University; surgeon to the Columbia and Sibley Memorial hospitals, surgeon in charge of diseases of women in the Central Dispensary and Emergency Hospital; and consulting gynecologist to the Eastern Dispensary; died at his home in Washington, May 8, from uremia, aged 61.

James Decker Spencer, M.D. Bellevue Hospital Medical College, 1870; a member of the Medical Society of the State of New York, and president in 1896; formerly president of the Jefferson County Medical Society; a member of the American Public Health Association, and New York Academy of Medicine; local surgeon for the Rome, Watertown and Ogdensburg Railroad; surgeon to the Jefferson County Hospital; and president of the medical board and consulting surgeon to the Watertown City Hospital; died at his home, May 5, from cerebral hemorrhage, aged 60.

George Arnold Bellows, M.D. Detroit Medical College, 1881; a member of the American Medical Association; physician to the Seneca County (N. Y.) Almshouse from 1884 to 1892; health officer of Waterloo from 1882 to 1883; U. S. pension examining surgeon from 1887 to 1895; coroner of Seneca county for several years, and since 1891, a member and secretary of the board of trustees of Waterloo Academy; died at his home in Seneca Falls, May 10, from acute nephritis, aged 53.

Charles S. Martin, M.D. University of Pennsylvania, Philadelphia, 1890; a member of the Medical Society of the State of Pennsylvania; recently appointed postmaster of Allentown; for ten years a member of the board of health; since 1897 a member of the board of trustees of the Allentown Hospital; secretary of the Hospital Association since 1892, and a member of the City Park Commission; died at his home, May 4, from heart disease, following pneumonia, aged 43.

Charles Austin Devendorf, M.D. Bellevue Hospital Medical College, 1866; for many years a practitioner of Detroit; a medical cadet, assistant surgeon and major of the line during the Civil War; professor and emeritus professor in the Detroit College of Medicine; one of the organizers and for several years chief of the medical staff of the Children's Free Hospital; died at his country home near Sandwich, Ont., May 3, from cerebral hemorrhage, aged 70.

John Joseph Gilhuley, M.D. Bellevue Hospital Medical College, 1894; of Bridgeport, Conn.; acting assistant surgeon in the Army during and after the Spanish-American War, with service in Porto Rico and the Philippine Islands; formerly city physician and fire department surgeon of Waterbury, Conn.; and later physician to the charities department of Bridgeport; died in Norwich, Conn., April 25, from acute nephritis, aged 36.

Elijah W. Jay, M.D. Cleveland College of Physicians and Surgeons, 1893; a member of the Iowa State Medical Society; coroner of Marshall county; member of the Marshalltown city council in 1895; who, while making an emergency run in an ambulance to a hospital with one of the victims of the Rock Island wreck at Green Mountain, March 21, was thrown from the ambulance, the fall resulting in a severe hernia, died in a hospital in Marshalltown, May 5, from pneumonia, aged 47.

Samuel T. Haffner, M.D. College of Physicians and Surgeons, Baltimore, 1874; a member of the American Medical Association, and once president of the Frederick County Medical Society; for several terms health officer of Frederick county and physician of Montevue Hospital, Frederick; elected clerk of the court in 1903; died at his home in Frederick, May 6, from angina pectoris, aged 61.

George W. Rohr, M.D. Northwestern University Medical School, 1862; Illinois Army Board, 1864; a member of the Illinois State Medical Society; surgeon of the Fifty-second Illinois Volunteer Infantry throughout the Civil War; local pension examiner; for more than forty years a practitioner of Rockford; died at his home, May 5, from heart disease, aged 76.

Jesse Lyman Conant, Jr., M.D. University of Vermont, Burlington, 1885; of Boise, Idaho; secretary of the Idaho State Board of Health; first lieutenant and assistant surgeon First Idaho Infantry, U. S. V. during the Spanish-American War with service in the Philippine Islands; died in the Josephine Hospital, Weiser, May 2, from cerebral hemorrhage, aged 54.

Francis Joseph Hilger, M.D. St. Louis College of Physicans and Surgeons, 1902; a member of the Iowa State Medical Society; lecturer on diseases of children in the training school for nurses at St. Joseph's Mercy Hospital, Dubuque, and a member of the medical staff of the hospital; died at his home in that city, May 3, from tuberculosis, aged 32.

John MacCurdy, M.D. Western Reserve University, Cleveland, 1858; Jefferson Medical College, 1859; a member of the Ohio State Medical Association; assistant surgeon of the Twenty-third Ohio Volunteer Infantry and a prisoner in Libby Prison during the Civil War; died at his home in Youngstown, May 4, from cancer, aged 74.

Benjamin R. Davidson, M.D. University of Maryland, Baltimore, 1867; for many years a practitioner of Anne Arundel county, Md.; and a resident of Davidsonville; physician to the county almshouse; treasurer of the county and register of wills; died in the Hebrew Hospital, Baltimore, May 1, from cerebral hemorrhage, aged 63.

George Briggs Richardson, M.D. Hospital College of Medicine, Louisville, 1890; formerly of Paradise, Ariz.; a member of the American Medical Association, and local surgeon for the El Paso and Southwestern Railroad; died at his home in Rodeo, N. M., May 2, from pneumonia, aged 48.

Henry Belt, M.D. Bellevue Hospital Medical College, 1898; a member of the American Medical Association, New York Academy of Medicine, and Medical Jurisprudence Society of New York; a specialist on neurology; died at his home in New York City, May 6, from pleurisy, aged 43.

William Troup Bell, M.D. University of Pennsylvania, Philadelphia, 1863; for several years superintendent of the City and County Hospital, San Francisco, and superintendent of the Masonic Home, Decoto, Cal.; died at his home in Lake Providence, La., April 30, aged 73.

James J. Linn (license, years of practice, Minn., 1887); for 52 years a practitioner of Minneapolis; one of the founders of St. Barnabas Hospital; and builder of the first isolation hospital in Minneapolis; died at his home, April 28, from heart disease, aged 83.

Cynthia Maria Nordstrom, M.D. Boston University School of Medicine, 1883; for sixteen years a member of the Malden (Mass.) School Board, and secretary of the medical board of the Malden Hospital; died at her home, May 4, from cerebral hemorrhage, aged 77.

Richard E. Garnett, M.D. University of Louisville, 1880; a member of the American Medical Association; physician of Barren county, Ky.; and secretary of the Glasgow Board of Health; died at his home in Glasgow, May 2, from heart disease, aged 54.

Robert S. McMurdy, M.D. Albany (N. Y.) Medical College, 1846; a member of the Minnesota State Medical Association; for 37 years a practitioner of Minneapolis; died at the home of his son in that city, April 29, from senile debility, aged 85.

Marshall P. Robinson, M.D. Eclectic Medical Institute, Cincinnati, 1876; formerly physician of Fayette county, Ky., and pension examining surgeon; died at the home of his sister in Lexington, May 6, from nephritis, aged 63.

Alvin Ephraim Wing, M.D. University of Colorado, Boulder, 1905; health officer of Rich county, and surgeon to the Utah and Wyoming Telephone Company; died at his home in Randolph, Utah, April 28, from erysipelas, aged 33.

James B. Robertson, M.D. University of Pennsylvania, Philadelphia, 1861; a surgeon in the Confederate service during the Civil War; died suddenly at his home in Clayton, N. C., April 28, from cerebral hemorrhage, aged 73.

Thomas Grant, M.D. Philadelphia University of Medicine and Surgery, 1876; of Liberty, N. Y.; died suddenly at the home of his sister in New York City, Dec. 30, 1909, from disease of the heart and kidneys, aged 73.

George Maxson Lamb, M.D. Hahnemann Medical College, Philadelphia, 1879; town physician and health officer of Hoosick Falls, N. Y., for twenty years; died at his home, May 3, from sarcoma of the throat, aged 52.

Samuel Charles Weeks, M.D. Tulane University, New Orleans, 1893; a member of the Louisiana State Medical Society; died at his home in New Orleans, April 28, from tuberculosis, aged 43.

James A. Ogden, M.D. University of Pennsylvania, Philadelphia, 1874; of Deadwood, S. D.; formerly of Parchalville, Philadelphia; died in Bunker Hill, Kan., April 24, from erysipelas, aged 61.

Edwin G. Keifer, M.D. Cincinnati College of Medicine and Surgery, 1869; a member of the Illinois State Medical Society; died at his home in Harvey, April 29, from arteriosclerosis, aged 66.

Louis Gustav Bauer, M.D. University of Pennsylvania, 1872; a member of the American Medical Association; died at his home in Germantown, Philadelphia, May 5, from cancer, aged 64.

Robert Martin, M.D. Starling Medical College, Columbus, Ohio, 1875; from 1881-1890, health commissioner of Milwaukee; died at his home in that city, May 2, from nephritis, aged 69.

Andrew J. Pennington, M.D. University of Alabama, Mobile, 1878; a member of the Louisiana State Medical Society; died at his home in Gibsland, April 26, from heart disease, aged 62.

William B. Robbins, M.D. Jefferson Medical College, 1873; of Catawissa, Pa.; died in the Jefferson Hospital, Philadelphia, April 29, after an operation for mastoiditis, aged 56.

Robert D. Gwin, M.D. Jefferson Medical College, 1855; surgeon in the Confederate service during the Civil War; died at his home near McKenzie, Tenn., April 29, aged 83.

George Washington Greaves, M.D. Rush Medical College, 1874; of Spencer, Iowa; died at the home of his son in Sturgeon Bay, Wis., April 22, from dropsy, aged 58.

John M. McKeage, M.D. University of Pennsylvania, Philadelphia, 1847; formerly an employee of the St. Louis health department; died in St. Louis, May 1, aged 85.

Severn M. Kelly, M.D. University of Minnesota, Minneapolis, 1905; formerly of Canby, Minn.; died at the home of his sister in Mankato, Minn., April 25, aged 30.

Hardy Murfrees Banks, M.D. New York University, New York City, 1851; of Englewood, N. J.; died at the home of his daughter in New York City, May 5, aged 79.

Tunis Housel Fisher, M.D. New York University, New York City, 1889; died at his home in South Brooklyn, May 7, from cerebral hemorrhage, aged 57.

John Henry Stemple, M.D. University of Maryland, Baltimore, 1901; died at his home in Conshohocken, Pa., April 19, after a short illness, aged 33.

Maurice Henry Walsh, M.D. Yale; formerly a practitioner of New Haven, Conn.; died in Fort Worth, Texas, April 4, from heart disease, aged 45.

Ernest Hamilton Smith, M.D. Tulane University, New Orleans, 1880; died at his home in Lacour, La., March 18, from heart disease, aged 54.

Frederick Castle, M.D. University of Michigan, Ann Arbor, 1869; died at his home in Lowell, Ind., April 19, from cerebral hemorrhage, aged 69.

Thomas F. Williams, M.D. Eclectic Medical Institute, Cincinnati, 1888; died at his home in Des Moines, April 25, from pneumonia, aged 46.

Joseph Goffin Bailey, M.D. University of Buffalo, N. Y., 1871; died at his home in Santa Ana, Cal., April 29, from heart disease, aged 65.

Alonzo Edson Robertson, M.D. Rush Medical College, 1893; died at his home in Mason City, Neb., May 3, from pneumonia, aged 38.

Edward James Rothe, M.D. Dublin; died at his home in Harison, N. J., April 21, from nephritis, aged 50.

Walter S. Dick (registration, Okla., 1908); died at his home in Baum, April 18, 1909, from pneumonia.

Society Proceedings

COMING MEETINGS

AMERICAN MEDICAL ASSOCIATION, ST. LOUIS, June 7-10.

American Academy of Medicine, St. Louis, June 4-6.
American Assn. of Medical Milk Commissions, St. Louis, June 6.
American Association of Medical Examiners, St. Louis, June 5-6.
American Gastro-Enterological Association, St. Louis, June 6-7.
American Proctologic Society, St. Louis, June 6
American Society of Tropical Medicine, St. Louis, June 11.
American Urological Society, St. Louis, June 6-7.
Assn. of Amer. Teachers of Diseases of Children, St. Louis, June 6.
Connecticut State Medical Society, New Haven, May 25-26.
Maine Medical Association, Bar Harbor, June 29-30.
Massachusetts Medical Society, Boston, June 7-8.
Nat. Con. State Med. Exam. [illegible] t. Louis, June 6.
New Jersey Medical Society, [illegible] 3-30.
North Carolina, Med. Soc. of [illegible] Beach, June 21.
Rhode Island Medical Society, Providence, May 31.
Wisconsin, State Medical Soc. of, Milwaukee, June 22-24.

AMERICAN PEDIATRIC SOCIETY

Annual Meeting, held in Washington, D. C., May 3-5, 1910

The President, DR. D. L. EDSALL, in the Chair

Officers Elected

The following officers were elected for the ensuing year: President, Dr. Henry D. Chapin, New York; vice-president, Dr. J. Mason Knox, Baltimore; secretary, Dr. Samuel S. Adams, Washington, D. C. (reelected); treasurer, Dr. Charles Hunter Dunn, Boston; recorder and editor, Dr. L. E. La Fetra, New York; member of council, Dr. Isaac A. Abt, Chicago.

Lake Mohonk was selected as the next place of meeting.

President's Address: Importance of Pediatrics

DR. DAVID L. EDSALL, Philadelphia: The honor of serving for a year as the president of a group of men who are the highest representatives of their type of work in this country imposes on one the duty not merely of giving expression to complacent satisfaction, but also of devoting serious thought to the activities that may be open to the members of the society, as individuals or as a group of men, by which they might still further advance the honorable standing of the work that is their chief concern in life. Proper dignity and regard are not yet accredited in this country to a subject which has proved to me unquestionably the broadest, most complex, and most important division of general medicine; and proper standing will not be generally given to pediatrics in this country until better things are demanded for it by concerted action and by a large group of those who are the recognized leaders. The dignity of the intellectual results are determined by two things: first, by the opportunities offered those who teach the subject and by the manner in which these opportunities are made use of; second, by the extent to which those who follow that pursuit engage in matters that vitally affect the welfare not only of individuals with whom they come in immediate contact but rather of the public at large. There are ways in which great usefulness can be secured for pediatrics in both of these directions and the society, by the strength of carefully planned concerted action, could rapidly and greatly benefit the position of the work which it represents. The methods pursued by the teachers determine the standards demanded in the subject and the quality of the future exponents of the subject. Among the teachers of this subject there are men who have in certain ways no superiors in any part of the world. Concerning the provisions made for their teaching, however, there are points which may be justly commented on and not wholly favorably. Pediatrics is probably more inadequately provided for in most medical schools than any other important subject. This criticism is of the general group of schools, not of individual schools. In some the system of teaching is relatively excellent; but nowhere is such good provision made for the subject as that which is made for general medicine, surgery and obstetrics. Neurology, I think, has much more actual standing and recognition in the best medical schools than has pediatrics. Yet the problems of infancy and early childhood are much more distinct from general medicine than are the problems of neurology and more properly demand generous provision for instruction. At present, there are in this country at least twice the number of men of recognized distinction in neurology than there are in pediatrics. The explanation is patent: while the responsibility may be properly thrown in part on the shoulders of the administrators of medical schools it cannot be put wholly on them but must be shouldered by pediatrists themselves. It is a common and seemingly just statement that the clinical branches have in this country in the past generation by no means kept pace with the medical sciences in methods of teaching and investigation.

There should be better general conditions in teaching; it is a well-recognized fact among educators that unless a man does some kind of research, more or less continuously, he does not make, or at any rate does not long remain, a sound teacher; because the teacher, in order to make the student search for knowledge, must search continuously and diligently himself. The kind of research work done in any particular department is commonly accepted, and rightly so, as the best criterion of the character that the teaching in that department will exhibit. The chief essentials for making well-trained men and for attracting first-class men into a subject are that the men shall do most of the work themselves and not be merely told about it; that they shall be made precise and critical in their methods and that the craving for a sound understanding for the reason of things be satisfied by having them clearly comprehend the relation between the fundamental and the practical things. In these ways general medicine and general surgery have been transformed within two decades and now students do most of the work in the wards and dispensaries; in pediatrics the changes have been less distinctive. Cases are less frequently seen as problems to be worked out by the student himself. The propriety of studying pediatrics as a special subject rather than as a mere part of general medicine is based essentially on the fact that the infant and young child differ from adults enormously in degree and almost equally in kind, in susceptibility to infections and especially in liability to derangements of nutrition. This gives a greater justification for specialization than any based on difference in the organs of the body.

The difficulty in regard to the studying of cases can be overcome only by demanding that the clinical work in pediatrics shall be put on the same basis as that which is being struggled for and increasingly secured in medicine and surgery. The society could wisely take on itself a serious consideration of the manner in which teaching and investigation in this branch may be benefited and by individual and concerted action further whatever appears to be wise. In this way he thought results could be rapidly accomplished. Among other ways in which the society could take a useful part is a study of school conditions, and the industrial conditions among children, which should be studied by persons of calm and judicial temperament so that we may be informed on the actual state of affairs by those whose opinion would be more reliable than that of perhaps over-enthusiastic philanthropists.

Experimental Study of the Food Reactions in the Infant Stomach, Compared with Those in Vitro

Drs. D. M. Cowie and William D. Lyons, Ann Arbor, Mich.: Because of the many discordant views as to disturbances of infant digestion we have endeavored to ascertain how food reactions in the infant stomach compare with those *in vitro*. We determined first the stimulating effect of normal food; how it is altered by certain chemical substances and how that compared with results obtained in test tubes. We found that the stomach is capable of stimulation from the first day of life; that all the ferments are secreted at that time. The secretion of acid was represented by curves which gradually rise. Taking samples of stomach contents from time to time a curve characteristic of the majority of infants was obtained. We made from 150 to 200 analyses on 28 or 29 infants and rarely found free hydrochloric acid present in the stomach. It is not necessary in order for the stomach to perform all its physiologic functions. After fasting for 6 or 8 hours we found hydrochloric acid, but at the end of the feeding period or in the middle we rarely got free hydrochloric acid. We determined that the basic condition of calcium casein must be overcome before the rennin precipitate rennin curds. Conditions are different from those in test tubes. The statement that basic calcium chlorid hastens evacuation of the stomach is not true. Taking out fats and anything that would inhibit motility of the stomach we found that in 45 minutes the change had taken place producing the ordinary curd. Basic calcium chlorid did not prevent formation of curds in the stomach in the majority of cases. We also showed that acidity hastened the opening of the pylorus, and we believe that this had more to do with the evacuation of the stomach than the curds. The curds were easily crushed and large curds did not occur in normal conditions of the stomach. Calcium chlorid curds were easily precipitated. We concluded that it was not necessary to produce a perfectly soft curd, but to learn what chemical changes actually go on in the stomach. The acid control of the pylorus is of great importance.

Estimation of Chlorids in the Stomach Contents from Normal and from Atrophic Infants

Dr. A. H. Wentworth, Boston: This paper is a continuation of work alluded to in a previous article, the principle of the research being the discovery that hydrochloric acid is diminished in the stomach contents of atrophic infants. The secreting power in cases of infantile atrophy was much diminished. The stomach of atrophic infants probably fails to secrete sufficient hydrochloric acid to stimulate the duodenum. In the first series of cases the stomach contents were obtained one hour after eating and determination was made. Results showed diminished secretion of hydrochloric acid in every case. The same experiment was made with healthy infants with variable results; in 4 cases it was greater and in 3 cases it approximated that of the atrophic infants. The results were not conclusive and a second series of observations were made. This article gives the results of the second series and certain conclusions that may be drawn from them. Unfiltered stomach contents were used in every case; soft rubber No. 19 French catheters were used; the stomach contents being obtained with the infant lying on its side. The diagnosis of infantile atrophy was made from clinical evidence alone. The possible relation of stomach contents to degree of acidity appeared not to be present in this series. A few infants showed marked gain in weight with only a trace of hydrochloric acid in the gastric juice. There was rarely more than a trace of hydrochloric acid from the stomach of atrophic infants fed on cow's milk. The results corresponded closely with those of the experiments previously made. The stomach contents of well-nourished infants fed on cow's milk showed diminished amount of hydrochloric acid, corresponding closely to about one-half of the atrophic infants. Although the diminution was marked, it was never so extreme as in the atrophic infants. The results tend to prove that marked diminution of hydrochloric acid occurs in infantile atrophy. It was also shown that these infants can gain markedly in weight without hydrochloric acid in the gastric juice, and that there is greater variation in hydrochloric acid in the stomach contents of these infants than in normal infants.

A Study of the Gastric Contents and Motility in Breast-Fed and Bottle-Fed Infants

Dr. Henry Heiman, New York, exhibited charts showing the experiments that were conducted in the childrens' ward at Mount Sinai Hospital, the study having been for the purpose of adding to the data on the subject of gastric digestion in infants. The first group consisted of 20 normal infants from 3 to 7 days old; in the second group were 13 artificially fed infants from 3 weeks to 7 months old. In all the temperature was normal for at least a week and the condition good. The method of procedure was, with the new-born, to weigh the baby before and after nursing. At the end of one hour the stomach contents were removed with a French catheter. No preliminary lavage was performed. In the second group 4 examinations were made for each case. The stomach contents received in a glass jar and measured in graduate, then filtered and the filtrate used for the tests. In the first group 30 specimens were examined. The quantity of milk consumed at each feeding was from 30 to 200 grams—considerably above the figures usually assumed at that time of life. In general, the pepticaction was more at the end of one hour than at the end of a half hour. The work showed in new-born infants the large amount of milk taken at one nursing; that total acidity was practically the same at the end of one hour as at the end of a half hour;

absence of free hydrochloric acid in all cases; presence of rennin in two-thirds; presence of lactic acid in one-half of the cases. In the second group pepsin was present in only 6 cases; rennin in but 2. I think that it remains for future study to place the matter of gastric analysis of infants on as firm a basis as that of adults.

Studies of the Effect of Varying Quantities of Fat and of the Presence of Various Salts on Digestion and Metabolism

Drs. Charles F. Fife and B. S. Veeder, Philadelphia, undertook studies to determine the absorption of fat in cases of chronic intestinal disease in infants. The infants were placed on definite formulas for some days and the urine and feces completely collected. Case 1, infant nine months, weight 10 pounds 9 ounces. Case 2, aged 10 months, weight 11 pounds 10 ounces. Tables and charts were exhibited to show the varying formulæ. The work showed in both cases that fat absorption was below that of healthy infants. The total amount was less the less fat ingested. When little fat was given the percentage of absorption was much less. The amount of carbohydrate present had no influence on fat absorption. Evidence pointed to the necessity of the splitting of fats before digestion. They found that in the low fat periods the actual amount of soaps in the feces was higher than in the high fat periods. The lower the fat ingestion the higher the amount of soaps. The work showed lowered fat absorption in these two cases of chronic intestinal disease while most writers claim that there is not much difference. They did not find any definite relation between the calcium, in the fat, the calcium in relation to the total amount of fat, or relation to the soaps in the feces.

Results of Substitute Feeding in Premature Infants

Dr. Maynard Ladd, Boston, concludes from a study of 125 cases of infants, in which the total mortality was 65.6, no infant under 6 months surviving, that modified milk must be considered as unsatisfactory food for premature infants and should be used only when breast milk connot be obtained. Incubators were not employed.

Effect of High-Fat and Low-Fat Diet on the Nitrogenous Metabolism of Infants

Drs. John Howland and Robert A. Cooke, New York, presented the results obtained with 3 infants put in a metabolic apparatus:

On a fat-free diet all the calories could not be supplied. On a high fat diet the caloric value rises. The protein given represented 6/10 gm. nitrogen per kilo. The first boy began with practically fat-free diet which was increased gradually until he was taking 76 gms. a day of food containing over 7 per cent. of fat; he was kept on this 2½ months, then reduced to fat-free diet. When on fat-free diet the stools were brownish, frequent and thin; as it increased they became light, and on high-fat diet whitish. A second child, boy of 6 months, badly nourished with ischiorectal abscess, had stools brownish and of very foul odor, as the fat intake was increased they became light and finally white and almost dry. The ammonium output was relatively high throughout. On medium-fat diet the child did best. In Case 3 the child was a small badly nourished infant of 5 months; the investigation lasted 3 weeks. At first he took fat-free food, then it was increased rapidly. He never did well at any time; showed definite reaction to all fat feeding. The first child showed only benefit; the second with excessive amount of fat showed disturbance and the last child was upset by a moderate intake of fat. The results showed the danger of trying to draw definite conclusions from limited material. We do not advise the use of too much fat, but the individual tolerance of some infants is so great that the greatest variation may not produce any harmful results. The best diet is one containing fat and sugar both in moderation.

Nutrition of the Feeble Infant: (a) Motility of the Stomach; (b) Results of a Trial of Finkelstein's Method

Dr. Henry D. Chapin, New York: The proper nourishment of feeble infants is a problem that taxes the resources of the most skilful pediatrist. Digestion and assimilation may be poor, either by inheritance or from faulty feeding, and when from any cause, the general vitality of the infant is lowered, the digestive tract is usually the first to suffer and the last to recover tone. Improved diet and hygiene offered the only successful treatment; drugs are of little or no avail. In normal infants during health no great difficulty is encountered in reference to the kind and quantity of food. In feeble and badly nourished infants, however, the weak action of the stomach, especially in its muscular power, is the source of much trouble. With this in mind, a series of 21 infants were studied with regard to gastric motility. The ages were as follows: Two weeks, 1; three weeks, 1; six weeks, 1; two months, 1; three months, 6; four months, 4; five months, 2; six months, 1; seven months, 1; twelve months, 3. These infants were taken from the wards of the hospital and represented all grades of malnutrition from the begining cases to those in the last stages of atrophy. It was not possible to form any definite conclusions as to gastric motility based on the age of the child from these cases. Of 19 examined at the end of 3 hours, only 6 could be shown to have approximately empty stomachs, and these 6, with one exception, were holding their own and in no case could free hydrochloric acid be determined. In 13 out of the 19 it was absolutely demonstrated that there was a considerable residual amount of food still remaining in the stomach. Butyric acid fermentation was marked in 6 and in 2 in which the stomach was apparently empty there was found a trace of butyric acid. In 7 cases examined at the end of 3½ to 4 hours 5 were surely empty; of the remaining 2 cases one showed many curds at the end of 4½ hours, while the other showed only a few small curds. Few if any of the children were normal and conclusions drawn from the cases had value only as a study in the nourishment of a feeble child. There is little doubt that in a large majority of cases the feeble infant with digestive disturbance is fed at too frequent intervals; too often a second feeding being given before the previous meal has passed through the pylorus, with the result that each successive feeding is contaminated; in the feeble infant gastric motility is greatly decreased and it is often necessary to increase the intervals between feedings. There is an analogy between this state in the infant and the condition known as myasthenia gastrica in the adult, an important element in the treatment of which is to make certain that the stomach is never overloaded. The form of the protein has frequently an important place in the management of infants and changing the form of the carbohydrates also frequently shows a marked effect in the infant's progress.

In 20 cases I tried Finkelstein's method of feeding, based on the idea that instead of the fat or protein being the usual cause of trouble most digestive disturbances are due to the sugar of milk, and the principle of the new method being cutting down of the amount of milk sugar and of the salts, adding in place of this casein and fat, and substituting other forms of carbohydrates for the milk sugar. They were all hospital cases and presented the usual difficulties of infants previously badly fed. The stools generally became grey, homogeneous, with putty-like consistence; there was usually a tendency to constipation. The results were not very promising. Eight gained slightly in weight while twelve lost. I believe that when benefits follow this method of feeding the results are due more to the form in which the protein is given than to the lessened amount of sugar in the mixture. Judging from the character of the stools it might act well in certain forms of diarrhea.

Discussion on Infant Stomach

Dr. F. S. Meara, New York: Has Dr. Wentworth taken into consideration the relation of the fat to the quantity of hydrochloric acid? Does Dr. Cowie attribute the opening of the pylorus to the action of the acid on the gastric or duodenal side?

Dr. A. H. Wentworth, Boston: In Dr. Veeder's cases were the periods of feeding continuous or not and did one period run into another? Also, was the percentage of fat per gram ascertained? Is the greater percentage of all the fats excreted in the form of soap?

Dr. Henry D. Chapin, New York: So far as the incubators or padded cribs are concerned, I prefer the cribs as I have found that the best incubators are not as good as the crib. I prefer a varying temperature to the steady temperature of the incubators. I have never saved a premature infant without breast milk.

Dr. Isaac Abt, Chicago: I have been impressed with the discrepancy in results and various interpretations of those doing the chemical research work, though I believe that there would be important definite results ultimately. The dogmatic methods used in some quarters in making interpretations and attempting to make clinical deductions based on chemical results so far obtained is somewhat premature. Besides the chemistry of digestion there is a biology of digestion; the ultimate appropriation of the molecule and its combination with the cell is of more importance perhaps than the chemical details.

Dr. Samuel L. Bernstein, Cleveland: I agree with Dr. Chapin in regard to the advantages of the crib over the incubator; the electric heating pad with maternal feeding has been the means of saving a number of these premature infants.

Dr. D. M. Cowie, Ann Arbor: I am inclined to believe that it is the action of the acidity on the duodenal side that has to do with the retention of food in the stomach.

Dr. B. S. Veeder, Philadelphia: The experiments extended over 7 or 8 weeks—the child being first put on a formula for 3 or 4 days. Soaps were not tested for separately, but we did compute the percentage of soaps.

Dr. Henry D. Chapin, New York: It is of the utmost importance to have the meals properly spaced, as otherwise there remains a residuum of food in the stomach to contaminate each successive addition of food. This constantly recurring contamination and over-burdening of the stomach resulted in fermentation and in time gastric dilatation with loss in tone of the muscular coats of the stomach, thus explaining how a chronic digestive disturbance may lead to the condition known as atrophy. I am in sympathy with Dr. Abt in regard to studying these questions along the idea of biology.

Dr. John Howland, New York: The biologic question is largely hypothetical; it cannot be expressed in figures or in charts, and while very interesting it leads no further than to saying that in each individual there is an individual variation. Until the work was done in terms that could be expressed in figures there had not been a beginning.

Amyotonia Congenita

Dr. J. P. Crozer Griffith, Philadelphia: Ten years ago, Oppenheim in Berlin noticed a peculiar symptom-complex and reported a few cases but not in detail. These patients had a condition of flaccid palsy, which appeared to be congenital, varying up to complete paralysis, but no actual atrophy. He called this myotonia congenita. As the symptoms were so similar to myatonic congenita, I have called the condition described in this paper amyotonia congenita. I found in all 48 cases besides my own. In December, a child of 15 months was brought to me; no family history, except intemperance in both father and mother. A diagnosis of myolitis had been made. The mother said that the child had never been able to do anything with its hands; the position of the hands suggested tetany. Electric reactions did not give reaction for poliomyelitis or tetany, in fact no reactions could be obtained. Dr. Mills suggested that it was a case of myotonia and further investigation corroborated that. The child could not turn itself in bed; when seated in bed it flopped about in any direction; the head fell forward or backward, anywhere gravity took it. There was affection of sensation. Tendon reflexes were abolished; respirations were almost entirely abdominal, the respiratory muscles being affected. The child was thought at first to be very weak-minded. In four and a half months it has improved wonderfully. It can now take a biscuit in the hand and slowly lift it to the mouth and bite at it.

There seems to be reason to believe that the condition is congenital either in its manifestation or in its origin. It is an affection of the muscles not controlled by the cranial nerves. As to the pathology, there have been 8 observations more or less complete but no one has come to any positive conclusion. There was in most every instance loss of striation of muscles or less of nuclei. In some there was involvement of the anterior horns of the cord but this is not yet certain because the changes described were so slight. Spiller maintained that there was no change in the nerve centers. The disease must be distinguished from poliomyelitis and from hypertonia. Nothing much could be said as to prognosis. A number of patients have died from respiratory involvement. Treatment is hygienic, with electricity and massage. No Wassermann reaction was made in my case, but so far as I could learn there was no history or symptom of syphilis.

A Study of the Value of Brudzinski's "Neck Sign" and Contralateral Reflex in the Diagnosis of Meningitis in Infancy and Childhood

Dr. J. Lovett Morse, Boston: Brudzinski in a paper on "the contralateral reflexes in the legs in childhood," published in 1908, drew attention to a sign which he found in tuberculous and epidemic meningitis, and occasionally in other conditions, but never in healthy children. This sign was a concomitant reflex of the leg on one side when passive flexion of the leg on the other side was made. He concluded that in connection with other signs such as Kernig's and Babinski's, it was useful in the differential diagnosis of meningitis. In a later paper, he stated that further study had confirmed him in his conviction of the value of this sign. In 1909, Brudzinski published another paper in which he stated that in meningitis passive flexion of the neck forward causes flexion of the legs at the hips and knees and a marked flexion of the legs on the pelvis. He found this sign in 20 of 21 cases of tuberculous, in all of 11 of cerebrospinal, and in 2 of pneumococcus meningitis. I examined 400 children, either well, or ill, with diseases other than meningitis, as to the presence of this sign; 90 were well; 150 suffered from disease of the respiratory tract; 90 had various diseases of the gastroenteric tract; 31 had diseases of the nervous system other than meningitis; the remainder had a variety of diseases, typhoid, nephritis, influenza, heart disease, rickets, purpura, scarlet fever, measles, etc. Neither the neck sign, nor the contralateral reflex was elicited in any instance. I concluded from the study of these 400 cases that Brudzinski and his followers are correct in their statements that neither the neck nor the contralateral reflex are present in well children or in those ill with diseases other than of the nervous system, and that these signs are very seldom seen in diseases of the nervous system other than meningitis. Their presence in an acute disease is strong evidence of meningitis; their absence does not exclude it. The diagnostic value of the contralateral reflex is less than that of the neck sign. They occur in all types of meningitis and so are of no importance in differentiation.

DISCUSSION

Dr. Mathias Nicoll, New York, three weeks ago had a case in which he found the sign positive. When left an hour the child would give a decided contralateral reflex reaction, but if it was induced several times in succession there was much less marked reaction. He had also had an opportunity of trying it in a case of cerebrospinal meningitis in which he had been able to get a very positive response, though it varies in intensity.

AMERICAN GYNECOLOGICAL SOCIETY

Thirty-fifth Annual Meeting, held in Washington, D. C., May 3-5, 1910

(Continued from page 1630)

Officers Elected

The following officers were elected for the ensuing year: President, Dr. Reuben Peterson, Ann Arbor, Mich.; vice-presidents, Dr. John F. Thompson, Portland, Maine; Dr. John G. Clark, Philadelphia; treasurer, Dr. J. Wesley Bovée, Washington, D. C.; secretary, Dr. LeRoy Broun, New York.

Atlantic City, N. J., was selected as the place for holding the next meting.

Primary Carcinoma of the Female Urethra; Hematoma of the Broad Ligament Recurring with Pregnancy; Fibroid Tumor of the Ovarian Ligament

Dr. Walter P. Manton, Detroit: Primary carcinoma of the female urethra is among the rarest of malignant manifestations; a careful search of the literature up to 1910 gives the reports of but thirty-five cases, including my own, and failed to reveal the report of a similar case of hematoma of the broad ligament recurring with pregnancy. The onl references to the occurrence of fibroids of the ovarian ligament which I have been able to find are the two cases reported by Doran in 1896. In both of these cystic cavities existed.

DISCUSSION

Dr. Reuben Peterson, Ann Arbor, Mich.: I have had two cases of this rare affection, one of which I have previously reported. A woman on whom I operated four or five years ago had a carcinoma of the meatus which extended up into the urethra about half an inch. I removed it so radically that incontinence followed with subsequent prolapse of the bladder mucosa through the remainder of the urethra. The woman complained of this, and so I sewed up the opening and made an opening from the bladder into the vagina. Then she complained of incontinence. I did a colpocleisis and made an opening into the rectum. I reported this case at a meeting of the American Medical Association, but do so again now in order to give the subsequent history of the patient. That woman has passed her urine through the rectum ever since, and to-day she is as well and contented as one can be in that condition. I examined the urine two and a half years ago and she had no ascending pyelonephritis, which is interesting because it has been contended that where this communication is established with the rectum pyelonephritis will take place: but it has not occurred in this case. The second case of primary carcinoma of the urethra happened a short time ago. It looked like urethral caruncle. However, microscopic examination showed it to be primary carcinoma. In this case I removed about one-third of the urethra, and there has been no recurrence of the condition for two years.

Dr. Clement Cleveland, New York: I have had two cases of primary cancer of the meatus, in one of which I did a radical operation, and the disease returned. In the second case I resorted to the use of the actual cautery, and I believe that this treatment will afford permanent relief of such a condition when surgery is of little value. I have seen such positive results from radium in the hands of Dr. Abbe, not only in cases of cancer of the vagina, fascial cancer, cancer on the lip, gum, nose and ear, that I believe its application to cancer of the urethra would be of great importance. I feel very positive that if the radium is used in such cases we would see as good results in cancer of the urethra as in cancer of the lip, nose or the ear.

Dr. J. Riddle Goffe, New York: Did Dr. Peterson use the cautery in the removal of these growths?

Dr. Peterson: I did not.

Dr. Goffe: I have had one remarkable case of malignant urethral caruncle or primary carcinoma of the urethra. This was a number of years ago. The woman gave a history of having been operated on by Dr. William Lusk six years previously. She stated that Dr. Lusk told her at the time that she had cancer and he did not dare remove it, but that he would make a button-hole in the urethra to save it from irritation, and that this was the best he could do. For six years she was comparatively comfortable. She had control of the urine, but passed it through the button-hole in the urethra. At the time she came to me there was a cauliflower excrescence protruding from the meatus, which was of bright cherry-red color, exquisitely sensitive, and the source of constant pain. With the cautery I removed all the urethra and the surrounding tissue from the posterior angle of the urethra, taking all but one-fourth of the urethra at the neck of the bladder. She made a comfortable recovery from the interference, but inside of a year the disease returned with the greatest violence, involving all surrounding structures and becoming constitutional. She died with great suffering about a year after the procedure I had instituted.

Dr. Frederick J. Taussig, St. Louis: In a case of carcinoma of the urethra, that occurred in the practice of Dr. Dorsett and myself, the patient was kept under observation for a long time. I saw her in 1900, and at that time there was a caruncle, chronic urethritis, a retroverted uterus, and a relaxed pelvic floor. I operated for the retroversion and for repair of the pelvic floor, but did nothing further to the urethra. Three years later she returned with a history of bloody discharge for three weeks. She had been examined two months previously by an experienced man and nothing had been detected so far as the urethra was concerned. I found an infiltrating cancer involving the lower part of the urethra. Operation consisted in removing the entire urethra to the point of its entrance in the bladder, putting a purse-string suture around the opening that was left in the bladder so as to strengthen the muscular tissue there, and then, as a further precaution, removing the external inguinal glands on both sides, although there was no glandular enlargement at the time. The patient made a good recovery from the operation; there was slight partial incontinence. She was kept under observation for 9 months, and then small nodules were noticed in the inguinal region and also about the internal iliac vessels, the triangle between the external and internal iliac vessels. A second operation was done, removing these affected glands, although difficulty was experienced in removing the disease about the iliac vessels on account of adhesions. A year and a half after the primary operation the patient returned with recurrence in both inguinal regions and higher up about the aorta. She was kept at the Skin and Cancer Hospital 2 or 3 months under trypsin treatment, which at that time seemed to offer a possible excuse for its use, and with no benefit. She died, and at autopsy there was absolutely no recurrence at the primary site. The tissues about the urethra and bladder were absolutely free from carcinoma; but the glandular involvement was not merely confined to the lymphatics; it involved also the liver and spleen.

Dr. Seth C. Gordon, Portland, Maine: A woman of 70 had a growth for nearly a year about the urethra, and at the time she came under my care she had been treated by caustics for 6 or 8 months. The growth was as large as a walunt and bled on the slightest touch; I removed it with three-quarters of an inch of the urethra, bringing the remainder down and attaching it. The operation was done 4 years ago and there has been no return. Examination showed the growth to be carcinoma.

Dr. Hiram N. Vineberg, New York: Some years ago I had a case of primary carcinoma of the urethra involving the anterior third of the urethra. I did a thorough operation, went close to the vesical sphincter, and as a result there was slight incontinence. Prior to operation the woman had no pain or bleeding. Microscopic examination proved the growth to be carcinoma. I did a plastic operation later and in trying to build up the artificial urethra and bringing the stump of the urethra forward was only partially successful. The woman could retain urine while in bed for an hour or so. She was under observation three years and during that time there was no recurrence. I have not heard from her since. At that time I collected eleven cases of primary carcinoma of the urethra.

Dr. Francis H. Davenport, Boston: I saw a patient who had been under the care of a woman practitioner, who had tried the injection of serum for this condition of the urethra, and with some comfort to the patient, but not an arrest of the disease. When I saw the patient nearly one-quarter of the urethra was involved, so that it seemed absolutely impossible to remove everything radically. Radium was tried for several months, but not so thoroughly as the surgeon would like to have used it, owing to the fact that it could not be applied in the urethra itself on account of severe pain, but only externally from the vaginal side. Finally the growth became so large that there was retention of urine and a suprapubic fistula had to be made, which relieved the immediate symptoms, but within three months she died from exhaustion.

Dr. I. S. Stone, Washington, D. C.: Next to the report of individual cases it is essential to know something about how wide the excision should extend, and how far the malignant process extends when we begin to operate on patients with early manifestations of carcinoma of the urethra. All the cases of cancer in this region in my experience have ultimately resulted fatally.

Dr. Joseph Brettauer, New York: I have repeatedly had patients sent to me with a diagnosis of carcinoma of the urethra, in whom microscopic examination showed the lesion to be urethral caruncle. At times it is very difficult to decide whether the growth is malignant or not; as a rule, the younger the patient, the more malignant the growth.

Dr. Edward L. Duer, Philadelphia: Recently I did an extensive operation for a carcinomatous growth of the urethra which extended well into the end of the vagina. It was difficult to operate without enlarging the opening nearly into the rectum. I removed the growth and the wound healed. The condition returned in a short time after the operation, and I applied the *x*-ray to the external parts, but in the course of a few months the disease returned, and radium was tried. I commenced with a weak preparation, and it seemed to have little or no impression. The strength was then increased 100 per cent., and the patient improved and has continued to improve. Previous to this treatment she had been confined to bed for nearly a year. She had to be carried to the country and could not walk. She now goes shopping, and seemingly is perfectly well so far as the last examination showed.

DR. W. P. MANTON: I wonder whether or not all the cases so reported are really cases of primary carcinoma of the urethra. There are many cases of periurethral carcinoma that are mistaken for urethral cancer, and no doubt some of them belong to this class.

Improved Operation for Extreme Cases of Procidentia and Cystocele

DR. J. RIDDLE GOFFE, New York: Procidentia and cystocele are the results of three lesions: first, a descent or relaxation of the supports above; second, laceration of the perineum to the second degree; third, stretching and tearing of the fascia at the base of the bladder, producing a hernia. The support below is only indirect and of secondary importance. The true principle of support is that of suspension, and in order to secure a permanent result after operation the organs must be suspended or hung from above. The broad and round ligaments and the fascia lata are the proper tissues to utilize for this support. As a rule, these conditions obtain in patients at or beyond the menopause. In child-bearing women, especially if they desire children, the uterus should be carried into normal position and retained there by shortening the uterosacral and round ligaments. The bladder is then freed from all attachments to the vagina and lateral structures and carried up and spread out over the face of the uterus and broad ligaments. The vaginal sheath and wall are then cut away in the median line sufficiently to bring it up snug against the base of the bladder when stitched from side to side. If the perineum is torn to the second degree and a rectocele is present, the floor of the pelvis is restored. In patients at or beyond the menopause the uterus is removed, the broad ligaments beginning with the round ligaments at their upper borders are then stitched together across the pelvis from side to side, from the round ligaments down to the cardinal ligaments, thus turning the raw edges of the broad ligaments posteriorly. On the plane of tissue thus constructed, the bladder is spread out and stitched in such a way as to carry the organ high in the pelvis, thus restoring the base of the bladder as it is originally to a comparatively immobile foundation, and restoring the hinges and the cornua of the bladder as so graphically described by Dr. Kelly. The upper end of the vagina is also stitched to the broad ligament, bringing it up taut against the base of the bladder, the fascia lata is cut away and stitched as previously described and the perineum repaired. To accomplish this work it is necessary at the beginning of the operation to make a longitudinal incision in the vagina along its anterior wall throughout its entire length and dissect the bladder freely from all its attachments. The results in my opinion are satisfactory and permanent.

DISCUSSION

DR. CHARLES JEWETT, Brooklyn, N. Y.: I have had the privilege and pleasure of watching Dr. Goffe do this work, and his technic is the most complete and perfect of any I know. He concludes the operation by securely building up the perineal buttress beneath the bladder.

DR. I. S. STONE, Washington, D. C.: This method, or a slight modification of it, has given me the utmost satisfaction. I have no knowledge of any case of cystocele or prolapse having recurred if the work has been properly done.

DR. HENRY T. BYFORD, Chicago, described a modified operation which he does in these cases.

DR. SETH C. GORDON, Portland, Maine: I am satisfied that all of the work we have done heretofore in the effort to fix the uterus, after complete procidentia, has been of little avail. The uterus gives way after a while. Recently I have been removing the uterus in every case and stitching up remnants of the vagina to the broad ligaments, and fixing it as well as possible. I believe that we open a new line of work in that direction when we begin by removing the uterus.

DR. CLEMENT CLEVELAND, New York: I have followed the operation described by Dr. Goffe for some years. In my hands it has been successful in the majority of cases.

DR. C. C. FREDERICK, Buffalo, N. Y.: I have been doing this operation for 4 or 5 years, and I have taken the position that in case of advanced procidentia the removal of the uterus, as a part of the operation, is the *sine qua non* to success. I have done 75 or 78 of these operation for procidentia, and have invariably used catgut for suture material and have not had any ill results from it.

DR. J. M. BALDY, Philadelphia: This operation is so extensive in its denudative qualities and so dangerous in its possible results as to be absolutely unwarranted as a simple cystocele operation.

DR. LEROY BROUN, New York: I have often seen Dr. Goffe do this operation. I have done it myself, and I have had the privilege of seeing one of the patients on whom Dr. Goffe operated, and a more ideally perfect result I have never seen. The uterus was in excellent position.

DR. GEORGE GRAY WARD, JR., New York: Dr. Goffe taught me this operation five or six years ago, and since then I have done it in several instances. The results speak for themselves; I have not seen a failure from the operation when it has been properly done. The patient is satisfied, and that is the best part after all.

Intramural Sequestration and Fixation of Uterus for Prolapse When Pregnancy Is Not Possible

DR. PHILANDER A. HARRIS, Paterson, N. J.: I have subjected six women to a possibly novel procedure for the cure of procidentia uteri, and since these operations have been followed by gratifying results, I wish to describe the operation for whatever value it may possess for others. A median abdominal incision is made from one inch beneath the umbilicus for three or four inches, and through it the uterus is delivered. While an assistant grasps and draws the uterus well out of the incision, the cut edges of the parietal peritoneum are sewn to and around the uterus at the junction of the cervix with its corpus. This sewing crosses the broad ligament at either side about two inches away from the fundus uteri. After thus attaching the opposing cut edges of the peritoneum to the uterus and the broad ligaments, the suturing is carried upward to the top of the incision, thus closing the peritoneal cavity with the corpus and fundus still held in the grasp of the assistant, and, of course, outside of the peritoneal cavity. While the assistant continues to hold the uterus outside of the incision, a 5/16-inch iodoform gauze and rubber tissue drain is placed on top of the muscle and beneath the fascia to a point two or three inches to one side of the incision, at which point it is made to emerge from a small stab wound. The tapering tail of this drain is placed in the wound between the peritoneum and fascia. The anterior surface of the corpus and fundus uteri are next denuded with a knife, after which the fundus is seized with a hook or volsellum forceps, with which it is dragged upward as far as possible toward the umbilicus, and made to nestle in the incision anterior to the peritoneum and between the recti muscles. The fascia is next sewn from the umbilicus downward with running stitches of chromicized catgut. Wherever the corpus and fundus uteri are in contact with the fascia as it is being closed, the stitches are made to include sufficient musculature of the uterus to fix it in its sequestered position. The sewing of the skin with a running catgut suture completes the operation unless the patient is obese, in which case a small drain is placed between the fascia and the skin and made to emerge from a stab wound two inches or more to one side of the incision. The application of the usual gauze dressing and adhesive straps completes the operation. The draining tubes are partly withdrawn in two or three days, but generally not removed until ten days or more after operation.

(*To be continued*)

AMERICAN GYNECOLOGIC SOCIETY AND AMERICAN SURGICAL ASSOCIATION

Joint Meeting, held in Washington, D. C., May 5, 1910

What Are the End-Results of Surgery for Relief of Neurasthenic Conditions Associated with Various Visceral Ptoses?

To What Extent Do They Improve the Neurasthenic State Itself?

Dr. Edward Reynolds, Boston, in opening the discussion took up the etiology of the ptoses and their relation to neurasthenia. Satisfactory end-results depend on a successful initial study of the causation of the individual ptosis, and of its consequent relation to the neurasthenia. Technic is a subordinate matter. Ptosis is never a primary affection, but is always secondary to some other condition. The causes of ptosis are (a) local anatomic or developmental anomalies, and (b) general systemic mechanical conditions. The local causes of ptoses of pelvic viscera are inflammatory lesions, trauma, high rectovaginal septum, persistent ileolumbar ligament, and antiflexion of the cervix. Operations should be adapted to these causes. The general predisposing causes of all ptoses are (1) general muscular relaxation, and (2) static abnormalities, such as the round shouldered, hollow-backed position, pendulous abdomen, the over-feminine figure, and the habitual use of bad corsets. All these static variations are characterized by a forward displacement of the center of gravity. The mechanics of adjustment of posture are comprised in the use of therapeutic shoes and corsets. Mechanical therapeutics is always necessary in static cases. Ptosis is sometimes the result of neurasthenia, sometimes its cause. The main guide is the relative chronologic sequence of local and general symptoms. It is important to avoid operation in neurasthenics unless complete relief of the local symptoms can be expected. Subsequent care is important.

Dr. Joseph A. Blake, New York: Patients suffering from visceral ptosis and neurasthenia should be divided into two classes. First, those in which ptosis of the organ or organs contributes to the neurasthenic state simply by the effect produced on the organs themselves. In this category we have displacements of the kidney, uterus, colon, stomach, etc. The results of operations on this class are dependent on the degree in which the condition affected the neurasthenic state. In the second class of cases a vicious circle is established, and ptosis increases the neurasthenic state if it is not the underlying cause. Operations undertaken on patients of this class must have in view the relief of the autointoxication, otherwise they will only be productive of harm. Partial or total exclusion of the colon is a rational procedure in certain cases and good results may be expected, but the greatest care should be exercised in the selection of cases for applying this operation.

Dr. John G. Clark, Philadelphia: We have a defective individual, as a rule, to deal with from the start, and as the result of this defect we cannot hope for the same surgical results as we would get from operating on patients with acute diseases. The individual perhaps has had autointoxication from the beginning, or was imperfectly developed from the start, and therefore a bad surgical subject for immediate or ultimate results, and it is particularly in this class of cases where surgeons should make haste slowly. In the last five or ten years I have tried various types of suspension operations in visceral ptoses, such as the Coffey or the Deyea type of operation, and have not had more than 75 per cent. of functional relief after following these cases carefully. In those cases in which there is a structural defect, as shown by obstructive and retention symptoms, one does not hope to get more than 50 per cent. of functional relief.

Dr. Maurice H. Richardson, Boston: I approach the treatment of the neurasthenic for whatever cause, whether a definite, unmistakable pathologic lesion, or a ptosis, or a slight lesion, like a displacement of the kidney, with the utmost discouragement. One of my recent cases was a woman whose abdomen was covered with scars from repeated operations that had been performed without relief, her last state being worse than the first. Finally, it was found that this woman's gall-bladder was full of gall-stones, which were removed, followed by relief. As to enteroptosis and operations for large dilatations of the intestine, I can recall examples of cases in which I was driven to operation after these patients had gone to the neurologist, the gynecologist, and the general surgeon, and had been treated by them without relief, but with the same general results of discouragement. In one instance, 8 or 10 years ago, I resected the large intestine 2 or 3 times with the hope of affording relief, but the patient was in the same neurasthenic condition as in the first place. In addition to the operation on the intestine she had developed a large ovarian cyst, which was removed. Before operating on these patients we should be sure, in the *first place, that there is a lesion; second, that it is the chief* cause of the neurasthenia; third, we should see if it canont be cured without operation, but if operation is to be done, we should see to it that it does not subject the patient to too great a danger. I believe that neurasthenia is more of a disease than we give it credit for; that it is some central, organic or nervous condition on which operative surgery will have about as much effect as the surgical treatment of epilepsy, and Dr. Wood once said that it would do just as much good to amputate a toe as to resect the motor area of the brain for the relief of this condition.

Dr. Richard R. Smith, Grand Rapids, Mich., restricted his remarks to a general consideration of the etiologic factors to be considered in connection with visceral prolapse and accompanying neurasthenia in women who present themselves to the gynecologist for the relief of symptoms.

Dr. Lewis S. McMurtry, Louisville, Ky.: How often, after difficult manipulations in the abdomen in normal individuals, so to speak, do we leave in the haste of an operation the viscera disposed in every possible irregular manner, and yet these things correct themselves in normal individuals, and they necessarily have no connection with neurasthenia, so that we must have a little more evidence than we have at present that visceral ptoses are the principal factors in the production of this condition of the nervous system and metabolism of the body known as neurasthenia. As to the clinical side of the subject, my experience is like that which has been related by other surgeons. Operative procedures for all these ptoses, whether of the pelvic organs, the kidney, or the alimentary tract, have been unsatisfactory. Neurasthenia occurs in both sexes in all stations and all conditions of life, among the rich and the poor, and its exact nature or its pathology is as yet unknown, and until it is more definitely known the results are going to be as we see them reported at present. What we need is a definite statement as to the origin or cause of this condition which we know as neurasthenia.

Dr. William M. Polk, New York: In patients who present themselves with ptoses that have been described as belonging to the upper abdominal cavity, we have conditions that unquestionably we balk before, but here I am convinced that orthopedics furnishes a most efficient aid, and the lines laid down by Dr. Reynolds and by Dr. Lovett of Boston, who has been associated with him, will be the means of benefiting many of the conditions for which surgery heretofore has been considered the only means of relief. But the psychoneurologist should not be forgotten in connection with these cases. There is no reason why we as gynecologists and surgeons should bear all the burden in these cases. I have come to the conclusion that there is a conspiracy on the part of the neurologist to land on us a class of cases which he knows full well will test every particle of his acumen, and here is a brilliant opportunity for the psychoneurologist to exploit himself to the fullest extent. When these neurasthenics come to us we should say to them, first pass through the hands of a competent orthopedist; pass next through the hands of a conscientious self-doubting neurologist, but beware of the over-confident neurologist, and then you can say, madam, or sir, as the case may be, as you have reached the end of all things, so far as medical investigation is concerned, I am now more than willing to command all the resources of my refinement of the surgical art.

Dr. A. J. Ochsner, Chicago: I wish to subscribe to the axiomatic statements made by Dr. Blake in regard to the surgical treatment of these patients. There is no doubt but that neurasthenia can be greatly exaggerated or possibly caused by the results of enteroptosis, when these results produce obstruction either to the alimentary canal and interfere with nutrition and cause autointoxication, or when the condition gives rise to obstruction of the ureter, or causes an accumulation of mucus in the gall-bladder, and secondarily causes gall-stones. The relief, after an operation in such cases, even though the neurasthenia was possibly caused by this condition, must be in most cases exceedingly unsatisfactory, and due to two causes. We do not mechanically relieve the condition; no matter how perfect the operation may be, except in a few instances, as, for instance, in draining and suspending the gall-bladder in removing a hydronephrotic kidney. Dr. Reynolds' presentation is along the line of observations I have made and which caused me to suggest prophylaxis rather than treatment in this way. Many years ago, in studying the treatment of hernia in children, I found that they were cured spontaneously, provided conditions were secured in which there was absence of abnormal intra-abdominal pressure and traction, by placing these children in a position with the foot of the bed elevated at from 15 to 30 degrees. I found that in children with pendulous bellies the recti muscles came together if they were shortened, that the oblique muscles were strengthened, and that the intestines, instead of hanging at the bottom of the pelvis, after a few months' treatment would be in normal position. I found that this enteroptosis had resulted from improper feeding, from gaseous distention, and from other sources of abnormal intra-abdominal pressure. In some of the cases the increased abdominal pressure was due to severe straining from constipation, and with the relief of this the enteroptosis was decreased to a marked extent. I believe that by overcoming the causes of enteroptosis in children, we will prevent its occurrence in many adults.

Dr. Howard A. Kelly, Baltimore: I am convinced from the conclusive demonstration of Dr. Clark, Dr. Richardson and Dr. Lovett, that they have found the key to some of the underlying causes of these conditions, and that rational therapy is to be adopted on such general and orthopedic lines as they have outlined. I shall restrict my remarks to the various types of nervous systems associated with movable kidney.

Movable kidney is frequently found in neurasthenics. Movable kidney, associated with renal pain, may exist to such a marked extent as to bring on the neurasthenic state. The symptoms connected with movable kidney sufficient to justify operative procedure, are, as a rule, definite, and of a local mechanical nature. Psychotherapy is of little use as an adjuvant in treating neurasthenics and in relieving either local or general ptoses so long as a displacement of the kidney persists. On the other hand, psychotherapy and other forms of treatment which aim at building up the patient's general condition may seemingly effect a cure. In an analysis of 245 patients with nephroptosis, 78 or 31.4 per cent. had neurasthenia of varying degrees. I never operate on neurasthenic patients without definite local symptoms.

Dr. Willis G. Macdonald, Albany: Not all patients who suffer from ptsoses are neurasthenic. A large proportion of them do not present symptoms. In a number of these cases of neurasthenia associated with ptoses the responsible conditions are autointoxication from the intestinal tract and peripheral irritations from movable organs. I divide patients suffering from neurasthenia and ptoses into two classes. In the first class, we have those patients who travel from rest cure to rest cure, from one climate to another, and who are battle-scarred from their conflict with surgery. For this class surgery has no potency. There is no hope for relief from surgical intervention in such cases. On the other hand, there is a considerable group of cases in which the condition can be traced to an overloaded cecum and sigmoid—a constant filling of the intestinal tube, with a large, dilated myasthenic stomach lying on the symphysis pubis. Operation will relieve successfully a large number of such patients; yet unfortunately our clinical methods are not sufficient to determine always just which patients will be favorably influenced by surgical intervention and which will not, and in making statements to physicians and friends of such patients we should, as a matter of common honesty, express some doubt as to the ultimate results in this particular class of cases.

Dr. John K. Mitchell, Philadelphia: The whole causation of neurasthenia seems to be bound up in a kind of vicious circle where one symptom produces another until one positively cannot disentangle the chain. What do we know about the normal relations of the abdominal organs? What do we know about the position in which the various organs in the belly ought to be in the ordinary upright posture which we maintain a large part of the time? How much mobility should such organs as the kidney and liver have? Apparently, from the manner in which the intestines are distributed in the belly, they are not placed there like articles on a shelf to be maintained in one position, but they possess a certain amount of mobility. I see few neurasthenics in whom the kidney does not have more or less play, and slightly movable kidneys sometimes give worse symptoms and cause more trouble than freely movable ones, and a floating kidney, unless it results in a twisting of the ureter and stoppage of flow of urine, causing pain in the ureter and in other portions of that neighborhood, does not produce so much symptoms as the kidney that is only slightly movable, one in which it would be difficult for the surgeon to determine whether it is movable or not. Before operating on a neurasthenic patient the surgeon should have a definite idea as to whether or not a pathologic condition exists, what he is going to do and what he hopes to accomplish by the operation; otherwise the results from surgical intervention will be unsatisfactory.

Dr. William J. Mayo, Rochester, Minn.: I agree with Dr. Clark that the patients we have under discussion are wrong from the beginning, and my own feeling is that but a small number of them should be treated surgically. For some years at Rochester we have made a careful examination of all patients who presented themselves, no matter whether they had cancer of the breast or gall-stones, or what not, and to our surprise we find that about 25 per cent. of the women had retroposition of the uterus. We did not find that retroposition of the uterus was more frequent in the latter decades of life. Even young girls who came to us, in whom pelvic examinations were made through the rectum, had retroversion of the uterus in about the same proportion of cases as those women who had reached the menopause. Again, we found that 20 per cent. of the patients who came to us had movable kidney, and a very large majority of them did not have any symptom whatever. I think the neurasthenics, from a surgical standpoint, should be treated like the insane, in that we should take no cognizance whatever of their general complaints, but if they have sufficient local pathology to warrant operation we should operate on them, as we have no right to deny them the relief that comes from surgery. Doubtless many of these patients would be benefited by the Emmanuel movement or by Christian science, and many of us would gladly turn them over to a Christian scientist if we were convinced that the Christian scientists were really Christians, because it takes a Christian to handle these patients.

FLORIDA MEDICAL ASSOCIATION

Thirty-seventh Annual Session, held at Jacksonville, April 6-8, 1910

(Concluded from page 1632)

Diagnosis, Clinical Types and Treatment of Uncinariasis

Dr. D. L. McSwain, Arcadia, discussed in his paper particularly those marginal cases of uncinariasis which are easily mistaken for other diseases, resembling many times acute malaria; those cases complicated with malaria; the value of the stethoscope in diagnosis; the danger from pulmonary edema following the administration of thymol in acute nephritic cases. An infant 11 months old, with no history of ground-itch, four months previous to treatment showed indications of anemia accompanied by occasional ileo-colitis. Microscopic examination for uncinaria ova was negative. With the aid of the stethoscope a diagnosis of uncinariasis was made. Hemoglobin less than 15 per cent., respirations 80 to 100 per minute. Three courses of thymol were given and at the end of six weeks the child was normal. A point of interest under the head of prophylaxis that should be settled by the pathologist is whether the *Uncinaria radiata* produces in the human the local manifestation of the disease, and if so, whether or not it is carried to the intestines, producing the systemic symptoms. It is a well known fact to every one who spent his childhood in the country that about cow lots is the greatest danger of becoming infected with ground itch.

DISCUSSION

MR. RAMSEUR, Ph. G.: In the infant of 6 months, what was the source of infection by hookworms?

DR. D. L. MCSWAIN, Arcadia: In my opinion the infection was acquired by the child crawling on the floor. In the family where this case occurred the grandfather was sixty-five years old and the entire family were hookworm sufferers. I don't think for a moment that ground itch is the only source of infestation. There are too many evidences that it is not so.

DR. HIRAM BYRD, Jacksonville: A feature of the case cited especially interesting was the fact that it did not show any evidence of hookworm on microscopic examination. When we remember that the larva finds its way into the intestinal tract either directly or through the circulation it is from six to ten days before the eggs appear in the stools. I wonder if that is not an adequate explanation of the absence of ova in an acute case of hookworm infestation.

Occurrence of Intestinal Parasitic Infections Among the White Patients at the Florida Hospital for the Insane

DR. RALPH N. GREENE, Chief Physician, Florida Hospital for the Insane, Chattahoochee, reported in his paper, that "among 220 white men there were found 92 cases of uncinariasis, or a percentage of nearly 42. The 187 women examined showed a total of 87 cases of hookworm infection, or a percentage of nearly 47. Four per cent. more women than men show hookworm infection in this series. These results show for the total number of cases in the white departments of the hospital, a percentage of nearly 44. . . . It may not be inappropriate to state that 42 cases not showing hookworm infection, or a percentage of even ten, were infected with other forms of intestinal parasites, namely, *Trichocephalus trichiurius*, *Oxyurius vermicularis*, and *Ascaris lumbricoides*. Taking these other forms of intestinal parasites into consideration, in the computation of percentages, would reveal the surprising result that among the 407 cases examined, were found 221 cases of intestinal worm infection, or a percentage of 54. Roundworms were found associated with hookworms in two cases, one of these being in each sex. *Trichocephalus dispar* infection was noted with uncinariasis in 26 cases; sixteen among the women and 10 among the men. Triple infection was noted in three cases, all of whom were men, the parasites present being *Uncinaria americana*, *Ascaris lumbricoides* and *Trichocephalus trichiurius*. . . . Among the patients in this series are noted an actor, mechanic, housewife, educator, farmer, congenital deficient and several graduates from leading colleges and universities. . . . Cases are to be found in the different types of insanities, from the lowest to the highest form of psychosis. The congenital idiot, the simple dement, the precocious dement, the senile dement, manial-depressive cases, the morphinomaniac, the paretic and the paranoiac, all show a fairly equal distribution of the infection. It has been noted among the cases infected that no matter what the form of mental disease may be, depression exists, and those cases which ordinarily should show evidences of excitability and elation, are depressed and melancholy."

A Plea for a More Vigorous Campaign Against Malaria

DR. GRAHAM E. HENSON, Crescent City, under the above title, addressed the Association with a desire to "stimulate an interest that will result in a decrease of the scourge that constitutes such a large percentage of the morbidity in our Southern states." The education of the public, the destruction of the mosquito in larval and adult stages, the prevention of the development of the plasmodium in man, and the entire eradication of the parasite from an infected blood stream with isolation of the individual in so far as possible, were the classified prophylactic measures and methods stated as being necessary in a campaign to stamp out the infection.

DISCUSSION

DR. J. H. PIERPONT, Pensacola: In regard to the destruction of mosquitoes: During the yellow fever epidemic at Pensacola in 1905 I was city health officer and war was waged against the mosquito, primarily, of course, to stop the yellow fever. We found mosquitoes breeding in every conceivable place: little cups of water in the trees; in vases of broken crockery used in cemeteries for flowers; in roof gutters where limbs of trees had fallen and made dams, and only a few teaspoonfuls of water were necessary to breed many mosquitoes. We could find them everywhere. The war against them was waged successfully. That fall we destroyed practically all the mosquitoes and breeding-places in Pensacola. The city had charge of the work. We oiled large pools of water. In the ensuing summer Pensacola was practically free of mosquitoes. The people who had screened their houses the summer before and who screened them the next summr, who had mosquito bars put in in great numbers, in the middle of the summer of 1906 found no need for them. The screening around many of the porches was removed. But I am sorry and ashamed to speak of the blunder made in the following years in not continuing the work. Only $200 a year would be necessary to keep Pensacola free from mosquitoes; the city was urged to make the appropriation, and I urged it, but nothing was done. The next year (1907) we had mosquitoes, and there are more now. We had no malarial fever during the yellow fever epidemic, nor within the following two or three years, but it is now beginning to show up in the city and suburbs.

SYMPOSIUM ON PELLAGRA

DR. J. H. RANDOLPH, Tallahassee: "The Nervous and Mental Symptoms of Pellagrins and What Can Be Done for Them."

DRS. G. J. WINTHROP and H. P. COLE, Mobile, Ala. (by invitation): "The Value of Transfusion in Pellagra."

DR. RAYMOND C. TURCK, Jacksonville: "Pellagra Complicating a Laparotomy."

DR. G. J. WINTHROP presented the conclusions of himself and Dr. Cole based on studies by Lombroso, Babes, Tizzoni, Antonini and Gatti, and Marianni, that (1) Pellagra is an intoxication; (2) the toxic principles of pellagra exist in the blood of pellagrins and will produce pellagrous symptoms when transferred to other animals; (3) pellagrous serum exhibits definite precipitative, hemolytic and antitoxic properties; (4) an active immunity exists in cured pellagrins and an immunity can be artificially produced in animals.

"Our employment of transfusion in pellagra followed a series of laboratory experiments on blood transfusion in surgical shock in animals and was undertaken with the idea of combating the severe anemia noted in terminal pellagra cases and perhaps of transferring specific antibodies. The results obtained in this first transfusion, performed at the Mt. Vernon Hospital for the Insane, were so gratifying that we were led to try its value in other cases. The histories of twelve cases so far transfused are briefly cited. We would note that in a number of these cases we have been unable to secure donors recovered from pellagra, and healthy individuals, usually close relatives, have been employed. We believe that these non-pellagrous donors, chosen from individuals living under the same environment, eating the same food, and subject to the same possibilities of contagion, probably possess a certain amount of natural or acquired immunity.

"Of the 12 cases transfused six are dead and six are apparently recovered for periods of from five to twenty months. It must be considered that in these transfused cases every possible medical measure had been fully tried, and only continued downward course finally impelled transfusion. A mortality of 50 per cent. in such cases we consider low. It may be noted that of the six fatal cases three were evidently hopeless before transfusion. The seemingly remarkable results obtained in some cases have led us to attempt the operation in all cases, even though considered hopeless. We believe that earlier employment of transfusion would yield decidedly better results, at least it would furnish more reliable data on which to base an opinion as to the true value of transfusion.

"Feeling that transfusion is as yet in an experimental stage, we make no claim as to its final value. Our clinical and experimental experience suggests the following conclusions:

"1. A serum therapy will finally be established in pellagra. Until the perfection of this serum therapy transfusion may be offered to combat the existing anemia and possibly may be the means of transferring a degree of natural or acquired immunity.

"2. In certain selected cases, not benefited by medicinal agents, transfusion has been followed by immediate temporary and possibly permanent recovery.

"3. Without a thorough knowledge of the technic and dangers of the operation, or if the procedure is applied without careful selection of cases and donors, it will certainly be brought into an undeserved ill repute."

DISCUSSION

Dr. G. L. Winthrop, Mobile: In a large number of cases the nervous manifestations seem to appear first. With the average case I believe the extraordinary intestinal symptoms first show, then the characteristic dermatitis and then the terminal stage of the disease showing the poisoning of the nerve cells themselves. In a certain number of cases nervous symptoms do show first and prior to the characteristic dermatitis. In these cases I think we should observe particular care in diagnosis. In the early cases where the patient has been gradually losing strength and weight for a month or more these nervous symptoms may be neurasthenic. I have noticed one particularly in which the patient, a woman, was sent to us as a possible pellagrin. The nervous symptoms were present. She was treated first as a purely neurasthenic or nervous patient and confined to bed for a while, but one morning she was put on the porch for the fresh air treatment and was exposed to the direct rays of the sun; the next morning there was noticed on the dorsal surface of the hand the characteristic dermatitis, the earliest eruption in pellagra I had seen. That made us rather positive of the diagnosis, and shortly afterward she developed other typical symptoms of the disease. All of our cases exhibited nervous symptoms. Attention has been called to the number of cases which are called *sine* pellagra; that is, without the pellagrous eruption. I believe there are cases which we should diagnose pellagra without the typical secondary symptoms, the nervous symptoms or the extraordinary intestinal symptoms. Particularly in those case which have been confined to the house and not exposed to the direct rays of the sunlight which seems to be necessary to bring out this pellagrous dermatitis. I believe that if we observe these cases which come to us showing nervous manifestations first we will be able to show that a large number of them are cases of true pellagra and not cases of that indefinite neurasthenic diagnosis.

Dr. R. L. Harris, Jacksonville: I had occasion to examine a patient the other day, over the abdomen, and breast, and found a number of brown, distinct spots; the woman was afraid of pellagra. These spots had been appearing for years: none have disappeared; she is absolutely well, not nervous, no intestinal symptoms. What is thought about this development?

Dr. J. H. Randolph, Chattahoochee: Without other symptoms, I would not feel justified in making a diagnosis of pellagra in that case. I think it better to look for some other explanation of the condition. Dr. Turck's paper was interesting to me because of the question of operations among the insane. It is a question that has agitated the mind of those having the care of the insane, more or less, at different times, and I feel that it probably shows the utility of resorting to operations to those presenting symptoms, with the hope of effecting relief from harmful abdominal or pelvic disorders. Cases have occurred in which such operations have been of good effect and the symptoms found to be quite resistent to any other means of relief. Some one has asked me whether in these cases of transfusion it is customary to operate more than once. Some of the cases which did not have such favorable results apparently gave variable symptoms after the first operation, and the question naturally arises whether further operative procedure was taken with the view of adding to the benefits already derived. I go a little further than Dr. Winthrop and am inclined to think that these nervous symptoms are almost always among the first presented. The treatment by transfusion appeals to me as the treatment *par excellence* in such cases, not only in the later stages, which, as I have said, is the only procedure of benefit, but in the earlier stages. Of course, I feel we should appreciate the fact that it is an operation or procedure which should not be undertaken by inexperienced hands.

Dr. G. J. Winthrop, Mobile: In two cases referred to in my paper, one, a male, aged 42, very little blood transfused, showed slight improvement, but this did not continue and patient died a month later. The other, a woman, aged 22, showed some improvement after first transfusion. We did second transfusion because we believed she had not received a sufficient quantity of blood. At the time of the second operation some time had intervened and her condition was such that we noted no improvement afterward. Very few of the patients have been transfused more than once, because the cases were so severe when we saw them that they either began to improve in a few days or were in such condition that transfusion absolutely afforded no help. On several occasions there has been marked edema after the operation. In the cases in which improvement was noticed by gain in weight, there was a disappearance of anemia and general better attitude of the patient. We have found that unless this change for the better takes place within the first week, that the case usually goes on to fatal termination. The question of donors has given no end of trouble. When only a few patients recover from the disease out of a large number, it is difficult to get donors. At present we have but two cured individuals who act as donors and we have nearly used up the strain from these patients and have to go elsewhere for blood. Usually relatives of the patients do as well. We undertake the operation willingly with healthy adults, being careful of the history of other communicable diseases, and have found the results in those cases to be very good. Transfusion in pellagra is in the experimental stage. We make no positive claims for the operation. We intend following up the subject and whatever conclusions we come to will be given to the profession and we will acknowledge publicly either the mistake or the success of the transfusion method.

Dr. J. H. Colson: I wish to mention a case which might perhaps throw some light on the etiology of pellagra. We have had some interesting discussions on hookworm disease, and I refer to that in order to convey the idea that I wish to express in this instance. About a year ago a German, aged 20, from a poor family, poorly nourished, hygienic conditions bad, was placed in the hospital. When I first saw the boy he was anemic, abdomen distended, edematous. I thought he had Bright's disease. His urine was tested for albumin with negative results. A microscopic examination revealed nothing of consequence. I next thought of uncinariasis and put him on treatment for that. He responded readily and began to improve materially. After I had given two or three courses of hookworm treatment, I put him on a supporting tonic. Color began to return, his strength increased, and he was discharged in six weeks as cured. He could take care of himself and do considerable light work incident to farm life. He was out of the hospital only a short while when he developed an eruption on his hand, back of his neck and face; in fact, on all surfaces exposed to the sunlight, very much like a burn of the first degree. That condition prevailed for some days and became intensified, and his color changed to more of a dark or leathery tint. After a month or six weeks' treatment, he again became normal. What was this eruption? I was of the opinion that it might be a kindred disease to pellagra. Will hookworm disease superinduce pellagra or will it be a contributing factor in the disease? I simply state this to show that in my experience hookworm disease and pellagra may be associated or that the two can exist simultaneously. There is no question in my mind but that this was a case of pellagra associated with hookworms. There were no nervous symptoms to any noticeable extent.

Dr. J. H. Randolph, Chattahoochee: I think Dr. Colson is on the right line. At the Hospital for the Insane we have made a similar diagnosis of a case of pellagra associated with hookworm disease. Many of us no doubt have failed to recognize pellagra in the past. The reference to sunburned condition recalls some cases reported at the Illinois State Hospital. I heard an address at the Pellagra Conference last fall in which the physician in charge there spoke of a condition existing among his patients and having not recognized it he first attributed it to burns for which he had discharged several of his hospital attendants, thinking they had been careless with the patients. Particular remedies applied in the early stages of pellagra bring magnificent results; whereas, if it is left until the last stages there are no such good results.

Dr. E. Porter Webb, Ponce de Leon: Less than two years ago a patient came from Alabama to my office in the western part of the state, showing typical symptoms of hookworm disease. I put him on treatment and rid him of uncinaria, but in about a month he too had developed a case similar to what Dr. Colson reported; hands and face appeared as if burned, or as if iodin had been used on them; in fact, all surfaces exposed to the sun were in this condition. He had been kept in the house for a while, and then when he got outside this eruption developed. Not being acquainted with pellagra, I made no diagnosis, and the patient died. It seems that pellagra is inclined to follow hookworm disease.

Dr. Hiram Byrd, Jacksonville: To some extent transfusion has been employed elsewhere, and it seems a thoroughly rational method of treatment; probably when we arrive at a complete and satisfactory method, it will be in that direction. If not, some light will have been thrown on the subject nevertheless, and we will be aided in reaching the disease. But the phase of pellagra which is perhaps most interesting and on which most people keep silent, is the etiology. While the cornbread theory has popped up all over the country, still I fear it has put the profession in a wrong light before the people in general. There had been enough said about cornbread and pellagra in the public press and in a general way to give everybody the one idea, or to give the laity, with few exceptions, the idea that the whole medical profession attributes pellagra to the use of cornbread. So far as I understand, at the present time the evidence is totally inadequate to fix the etiology in any direction, and I think it is a serious mistake for the medical profession to commit itself at the present time to any theory. There is no conclusive evidence in that direction, and it appeals to me as a mistake which may have to be regretted and one which we may have to back down from.

Dr. G. J. Winthrop, Mobile, Ala.: Lavinder, in one of the publications of the U. S. Public Health and Marine-Hospital Service, has, I believe, rather concisely stated the existing theories as to etiology. He accepts the old classification, the broad one, of two groups: the zeists and antizeists; one claiming a definite relation between Indian corn and pellagra; the other denying this connection and believing that pellagra is simply a symptom-complex occurring in various alcoholics, insane persons and chronic diseases. I cannot but believe that Indian corn bears some relation to pellagra, and I believe that the general opinion of the country is in favor of some relation between Indian corn and pellagra. The work of the Illinois State Board of Health along this line promises a great deal of good. They went to work in a scientific manner, worked on it a number of months during the summer season, made careful blood examinations, examined the supplies of corn, and out of this came the conclusion that Indian corn bears some relation to the disease. I gather from some correspondence with the Italian physicians that there is a feeling among them that pellagra is a specific infection due to some microscopic organism, probably. I agree with Dr. Byrd, however, that the cornbread theory cannot be positively accepted now. I have had one or two patients who positively deny eating cornbread at all. One was a boy of 8, a definite case, with eruption on the dorsum of both hands, severe stomatitis and diarrhea; he had the disease three years. In Mexico, where cornbread is very common as an article of food and pellagra is almost unknown, the people keep the cornmeal in ovens before eating, thereby killing any organism present. In Italy ovens have been established where the disease is more prevalent, and a decrease in the number of cases is claimed since this method has been instituted.

Dr. Hiram Byrd, Jacksonville: Dr. Louis W. Sambon has recently presented evidence that to his mind excludes corn having anything to do with pellagra. A committee was appointed by the British Medical Association, composed of such men as Lauder Brunton, William Osler, Patrick Manson, Leishman, Ross, Sanwith, Simpson, Dawson and Williams, to investigate pellagra. After hearing Sambon's discussion of the subject, they passed a resolution that his idea was worthy of consideration, and proceeded to gather funds for investigating the disease. Sambon was appointed to have charge of the work. The investigation is to look into the question of the sand-fly as serving as a transmitter of the disease.

MEDICAL AND CHIRURGICAL FACULTY OF MARYLAND

One Hundred and Twelfth Annual Meeting, held at Baltimore, April 26-28, 1910

(Concluded from page 1639)

The Importance of Thorough Teaching of Infectious Diseases of Childhood in the Medical Curriculum

Dr. Clemens F. von Pirquet, Baltimore: The average student leaves our medical schools without having seen many of the infectious diseases of childhood. Several reasons may be assigned for this apparent neglect of a thorough instruction in these diseases. A large number of medical schools have no hospitals of their own in which such teaching can be carried on in a satisfactory manner. Those schools which are more intimately connected with well-equipped hospitals labor under the disadvantage that these institutions do not admit cases of infectious disease. One of the most prominent reasons for this is the expense entailed by a proper care of these cases. Many communities insist that a hospital for infectious diseases ought to be removed from the city limits. This is certainly true of those infectious diseases which do not occur regularly in a community such as plague, cholera, smallpox. But there is absolutely no necessity for this in the case of those infectious diseases which occur constantly, many foci of which still persist within the city limits. Particularly in severe cases of diphtheria is it important to be within as easy reach as possible of the hospital. In the teaching of infectious diseases, we must again make the separation into two main groups. In the one belong the sporadic infections not endemic in a community; in the other, the common infectious diseases. With regard to the former, we must demand of the practitioner that he be well enough acquainted with the usual infectious diseases to realize that a case of such sporadic disease, if he happens to meet it, presents features which do not belong to the common infections. With regard to the teaching of the second group, it is not sufficient to have read the text-books or to have seen as many cases as even a man with a large practice encounters. Only a special training in a hospital for infectious diseases can give the teacher sufficient experience to instruct the student properly. To sum up, we come to the conclusion that the medical student should get a good training in the ordinary infectious diseases of childhood, in order to make the diagnosis with certainty, even in somewhat atypical cases, in order to apply the right therapy, to be able to make a prognosis, and in order to take the proper prophylactic measure; and, finally, in order to distinguish a case of the dangerous, unusual infections which involve a real danger to the community. For this purpose, it is not sufficient for the student to get a theoretical course or to see a case in the dispensary now and then, but he should be taught at the bedside by a teacher who has himself a thorough training in infectious diseases. To this effect wards for the common endemic infections should be attached to the hospitals of the medical schools. From the hygienic standpoint, this is not only not objectionable, but has many advantages. I hope that this body will endorse the importance of these demands, and that the American Medical Association will take up the matter and bring it to the general consideration of the profession.

SYMPOSIUM ON UNCINARIASIS

Introductory Address: Importance of Uncinariasis

Dr. William H. Welch, Baltimore: Both the profession and the laity are interested in this important topic. One of the most remarkable things about the disease is the mode of infection. Even though the parasite is an entozoan it enters the body through the skin. The possibility of infection through the alimentary canal, however, cannot be excluded. In general, the more severe the infection the graver the symptoms, though there are exceptions to this rule. A point of dispute is as to whether or not the anemia of the disease is the result of the suctorial activities of the worm. The Porto Ricans claim that the parasite does not suck blood, but Whipple and others have shown that it does. The toxic theory of the disease is still in a hypothetical stage. The disease has received an odium, especially in the South, making difficult the campaign against its suppression. The work of the Rockefeller Commission, with the establishment of which Dr. Stiles had much to do, will be carried on in large measure through the medium of the local health departments. Success in the fight against the hookworm means a general improvement of living conditions in the South.

General Consideration of Uncinariasis

Dr. Charles W. Stiles, Washington, D. C.: The problem of uncinariasis involves practically the entire public health question in the South. In this country four different races are trying to live side by side—the white, black, yellow and red. It is impossible for four different species of animal to live together in this way. In 15 of the southern states the blacks form 34.44 per cent. of the entire population. In 8 of these states there are 833 blacks to each 1,000 of the whites. The cause of uncinariasis is the *Necator americanus*, on which the title of hookworm was originally bestowed by Fröhlich, who believed that the tail of the worm possesses hooks, though this is not true. In from 80 to 90 per cent. of all cases, and in all of the severe cases, infection takes place through the skin. A small proportion, including especially light cases, are the result of alimentary infection. The worms unquestionably suck blood, although this may not be observed if the cold worm is studied. The toxic theory deserves serious consideration. Among the common symptoms are anemia, prominent abdomen, the characteristic position of the hands due to the drooping of the shoulders, absence of the pubic hair, puffiness under the eyes, etc. The prevalence of the disease in the South is due (1) to the presence of the negro, and (2) to hygienic conditions; 61 per cent. of all the farms investigated in the South have not even a privy. The campaign against the disease must be one of cleaning up and of erecting sanitary closets throughout the South.

Uncinariasis: Its Frequency, Distribution and Importance in North Carolina

Dr. W. S. Rankin, Raleigh, N. C.: Uncinariasis is by far the commonest and most important disease of the South. Of 104 college students examined by Nicholson and Rankin, 52, or 37 per cent., were infected. These students represented 25 counties in the state. In the eastern counties the disease is certainly more severe and probably more frequent than in the western counties. It is most frequent on a soil composed of an upper layer of fine, gray, compact sand with a substratum of clay about 6 or 10 inches below the surface. It is almost entirely absent on a soil of coarse sand, 6 or 8 feet deep. When the two races are together the disease is far more frequent in the white. It is a disease of the barefoot period of life, and rural rather than urban in its distribution. The importance of the disease rests on its frequency and its far-reaching effects. As a direct cause of death in the South, it is rare compared to the number of those who have it. The indirect effect of uncinariasis, however, usually places its victim among those who "rarely die of the disease with which they suffer."

Climatic, Soil and General Conditions in Maryland with Reference to Uncinariasis

Dr. Marshall L. Price, Baltimore, based his paper on an exhaustive study of climatic, soil and hygienic conditions in Maryland, as a result of which he concluded (1) that uncinariasis is not now a prevalent disease in Maryland, and (2) that there is little probability of its becoming so in the future. This Dr. Price attributes especially to the general employment of the sanitary privy, and to the fact that practically all the people wear shoes.

Clinical History and Pathology of Pellagra

Drs. William F. Lockwood, Harvey G. Beck and Caleb W. G. Rohrer, Baltimore: One of the earliest descriptions of the disease was by Thierry in 1775, at which time the disease prevailed in the Asturias in Spain. Later it appeared in France and Italy and at present it is found in almost all the provinces which limit the upper zone of the corn belt in Europe. Owing to the short season, corn is cut unripe and becomes diseased, and the prevalence of pellagra in these localities is attributed to the eating of this affected corn. The disease is also found in certain regions of Africa and South America. Pellagra was first recognized in the United States only a few years ago by Searcy, who reported an epidemic in the insane asylum at Mt. Vernon, Alabama; since then the disease has been found to prevail in a number of southern localities. So far 7 cases have been recognized in Maryland, 4 of which have been treated at the Mercy Hospital and form the basis of this report. Clinically, pellagra is characterized by 3 well-defined groups of symptoms, viz.: (1) gastrointestinal; (2) cutaneous; (3) nervous. The gastrointestinal symptoms are anorexia, nausea and vomiting, burning sensation in epigastrium, diarrhea, stomatitis and salivation. The stomatitis is perhaps the most characteristic of these symptoms. The tongue has been termed the "cardinal" tongue because of its color and diagnostic value. The oral mucous membrane, as well as the anal, shows the same degree of congestion and redness. The most characteristic group of symptoms are the cutaneous. These appear symmetrically as an erythema resembling a simple sunburn on parts exposed, as the dorsa of the hands and the face or on pressure points in bed-ridden patients. Bullæ may form within a few days. The skin becomes dry and rough and assumes a characteristic chocolate color. Exfoliation takes place either in small bran-like scales or large masses of skin which frequently leave bleeding surfaces. After exfoliation the skin remains atrophied and has a smooth and glistening appearance. These lesions usually appear in the spring and frequently pass through all stages successively two or three times. The nervous and psychic symptoms are marked. Mental dulness and apathy are distinctive features. The expression is serious, the memory is poor and the patients are slow to comprehend. Melancholia is common and insanity develops in a considerable number of cases. Vertigo is frequently complained of. Reflexes may be disturbed and the gait affected by degenerative changes in the cervico-dorsal part of the cord. Pain and tactile sense may be entirely lost over the lesion. There are two forms of pellagra described: (a) acute typhoidal, (b) chronic recurrent. The pathology of pellagra is not constant. Different observers have described different pathologic findings. These, however, are usually discussed under three heads: (1) the changes in the intestinal tract; (2) changes in the nervous system; (3) changes in the skin. The changes in the intestinal tract consist of atrophy of the muscular coat, with intense hyperemia and occasionally ulceration. The most constant post-mortem change is alleged to be degeneration of the lateral columns of the spinal cord, most pronounced in the dorsal region. The skin changes are erythematous in type. At first there is congestion, followed later by pigmentation, and finally by desquamation. Our first autopsy showed an additional feature, namely, the presence of granulomatous bodies in the walls of the superficial blood vessels of the lungs and brain, and also in the stomach, intestines, spleen, kidney and uterus.

The Soy Bean as a Food in Diabetes

Drs. Julius Friedenwald and John Ruhräh, Baltimore: The soy bean (*Glycine hispida*), sometimes incorrectly called the soja bean, is an annual leguminous plant which originally grew in a wild state from Cochin China to the south of Japan and to Java. The soy bean has been known in the United States for many years, but until the last 15 or 20 years, only as a curiosity. A full account of the plant will be found in Farmers' Bulletin No. 58 of the U. S. Dept. Agriculture, and of the different varieties in the Bureau of Plant Industry Bulletin No. 98. The bean has been put to many uses. The yellow variety, grown in America, has the following composition: Water, 10.13 per cent.; protein, 34.63 per cent.; fat, 17.98 per cent.; nitrogen free extract. 30.50 per cent.; fiber. 3.69 per cent.; ash. 3.07 per cent. The most striking thing about the bean is the fact that it contains no starch. or, at least, a very small quantity, which is strange when one considers that it resembles the various beans very closely and that all other varieties of beans are extremely rich in starchy materials. The fact that the soy bean contains little or no starch suggests its use in certain diseases. One of us (Ruhräh) has already called attention to the use of the bean in infant feeding. It may be prepared in the form of gruel flour, gruels, broths, muffins, etc. In the eight cases of diabetes which we report the patients were placed first, on an unlimited diet, second, on the usual diabetic diet, third, on the usual diabetic diet together with the soy bean, the latter replacing largely the gluten or wheat bread. The percentage of sugar in the urine in these 8 patients with the 3 different diets, respectively, was as follows: Case 1, 1.5 per cent., 1.1 per cent., 9 per cent.; Case 2, 3.5 per cent., 2.1 per cent., 1.5 per cent.; Case 3, 3.2 per cent., 2.5 per cent., 2 per cent.; Case 4, 3.5 per cent., 2.4 per cent., 2.1 per cent.; Case 5, 2.2 per cent., 0.0 per cent., 0.0 per cent.; Case 6, 4.1 per cent., 3 per cent., 2.5 per cent.; Case 7, 3.8 per cent., 3.1 per cent., 2.6 per cent.; Case 8, 4.3 per cent., 3.4 per cent., 1.9 per cent. We conclude: 1. The soy bean is a valuable addition to the dietary of the diabetic on account of its palatability and the numerous ways in which it can be prepared. 2. The soy bean in some ways causes a reduction in percentage and total quantity of sugar passed in diabetic subjects on the usual dietary restrictions.

Diagnosis of Ulcer of the Stomach and Duodenum by the Roentgen Ray

Drs. Harry Adler and **H. E. Ashbury**, Baltimore: The recognition of ulcer of the stomach and duodenum is always so important and at times so difficult that any method must be welcomed which promises aid in those atypical cases in which the absence of the cardinal symptoms permits only a suspicion or at most a presumption. The finding of blood in the stool, either occult or visible, has proved of great importance, but since even occult blood is often absent for weeks at a time, this means of diagnosis is frequently unavailable. Murdock's orthoform test is usually untrustworthy. Our purpose is simply to call attention to the valuable aid the *x*-ray has furnished in a number of cases. There was little in the literature to aid us. Hemmeter in 1906 spoke of the diagnosis of gastric ulcer by means of the *x*-ray, and referred to successful results in cases of artificial ulcer produced experimentally in dogs and cats. Our method is to give a single dose of bismuth and wait a time sufficient for the stomach to get rid of it, having determined in advance the motility. The picture is taken usually from four to six hours after the bismuth, which is given on an empty stomach. We have not found that the spinal column or ribs interfered with the demonstration. Of the 6 cases we report, 3 were undoubted cases of ulcer clinically; 1 was proved by operation. In 2 the diagnosis could be but presumptive without the *x*-ray examination. In 3 of the cases radiographs were made again, after carrying out ulcer treatment. In 2 the ulcer shadow had disappeared, in 1 it persisted. While the number of cases presented is small, the results are such as to lead us to believe that radioscopy is an extremely valuable aid to diagnosis, second in importance probably only to hematemesis or melena.

Deductions from Ten Years' Experience with Local Anesthesia for the Operative Treatment of Ano-Rectal Affections

Dr. S. G. Gant, New York: This paper was based on an experience with over 2,800 cases of anorectal disease in which local anesthesia had been used.

Indications for and Relative Merits of Appendicostomy, Appendicocecostomy, Cecostomy, and Cecostomy with a Provision for Irrigating Both the Large and Small Intestine

Dr. S. G. Gant, New York, after an exhaustive consideration of these various operations, laid especial stress on his method of performing cecostomy, with a provision for irrigating both the large and small intestine. The apparatus used in this method was exhibited

Medical Economics

THIS DEPARTMENT EMBODIES THE SUBJECTS OF ORGANIZATION, POSTGRADUATE WORK, CONTRACT PRACTICE, INSURANCE FEES, LEGISLATION, ETC.

A National Department of Public Health

Since the last mention in this department the following bodies have passed resolutions endorsing the principles of the Owen bill (S. 6049) providing for a department of public health:

Ripley County (Ind.) Medical Society.
Columbia County (Pa.) Medical Society.
Lawrence County (Pa.) Medical Society.
Marion County (Iowa) Medical Society.
Gentry County (Mo.) Medical Society.
Washoe County (Nev.) Medical Society.
Winona County (Minn.) Medical Society.
Rutherford County (Tenn.) Medical Society.
Larimer County (Colo.) Medical Society.
Grafton County (N. H.) Medical Society.
Schenectady County (N. Y.) Medical Society.
Essex County (N. J.) Medical Society.
Worcester District (Mass.) Medical Society.
Wabash County (Ill.) Medical Society.
Nodaway County (Mo.) Medical Society.
Southeast Missouri Medical Association.
Tipton County (Ind.) Medical Society.
Camden County (N. J.) Medical Society.
Middlesex South District (Mass.) Medical Society.
Oklahoma County (Okla.) Medical Society.
Jefferson County (Ill.) Medical Society.
Parker-Palo-Pinto County (Texas) Medical Society.
Mercer County (Ill.) Medical Society.
Northern Iowa Medical Society.
Dekalb County (Tenn.) Medical Society.
Dover (N. H.) Medical Society.
Defiance County (Ohio) Medical Society.
Cass County (Ind.) Medical Society.
Nye County (Nev.) Medical Society.
Jefferson County (Ala.) Medical Society.
Philadelphia County (Pa.) Medical Society.
Genesee County (Mich.) Medical Society.
Washington County (Ill.) Medical Society.
Mahoning (Pa.) Presbyterian Men's Club.
New Hampshire Conference on Charities and Corrections.
Public Meeting of Citizens of Sydney, Ohio.
Physicians of Mandan, N. Dak.
Public Meeting of Citizens of Aledo, Ill.
Detroit Board of Commerce.
Oklahoma City Chamber of Commerce.
Physicians of Mason City, Iowa.
Citizens of Albany, Mo.
Citizens of Leadville, Colo.
Odd Fellows of Leadville, Colo.
Leadville (Colo.) Improvement Association.

NEWSPAPER COMMENTS

The following are a few of the editorial comments received:

The Natchez *News* says: "It needs no full elaboration of arguments to show that the health of approximately one hundred million inhabitants of the country is of equal importance with that of other matters of administration by the several departments. Laws as to sanitation, hygiene, prevention of disease, handling of epidemics, etc., can be carried out more successfully when the different bureaus now scattered in the several departments are consolidated into one in charge of a cabinet officer. . . . That the agricultural and industrial development of the country is possible only when the health of the country is good and that unnecessary waste of life and health are as injurious as the wasteful abuse of material resources is readily admitted by all. There is no doubt that if the bill is given careful consideration it will ere long become a law, to the lasting benefit of the country."

The Bellingham (Wash.) *Sunday Herald* says editorially: "Of all the plans of doctors and laymen none has in it greater merit and promise than that proposed by Senator Owen for the creation of a national department of public health. . . . We have been wasteful of our greatest national asset, the health of the nation, as we have been wasteful of our great natural resources. It is time to stop and take count—to notice what price we are paying—to see whether industrial supremacy is not costing too much, not only in wasted lives and in needless sorry and [illegible] ld, bare dollars and cents. It is a case not [illegible] and theorizing but for hard common sense [illegible] of such knowledge as we now have. Every public health officer in the land, from the official in whose keeping is the health of the smallest town to the commissioners of health of our greatest states, should be able to turn to a full-fledged, properly equipped and widely experienced department in Washington for advice, support and relief. In many cases the health of whole communities is now endangered for lack of a central department able to advise with authority and of sufficient prestige to have its requests listened to with attention. . . . As the national Department of Agriculture has been of incalculable benefit to the farmer and the state departments of agriculture, so will a national department of health help the state and municipal governments to carry into every household and factory in the land the new gospel of fresh air, of decent housing, of factory legislation and of wages sufficient to enable the wage earner to maintain what we regard as an American standard of comfort. Senator Owen has performed a great public service in proposing this first adequate solution of our difficulties. If Congress would realize the change that has taken place in public sentiment during the last few years and the weight of the public demand for this bill, of which evidences are at hand at every turn, it is possible that congressmen would hasten at the present session to heed the wishes and united demand for a thoroughgoing reform of our outgrown and inadequate public health ligislation."

The Flint (Mich.) *Journal* says: "We must agree that it is quite as necessary to save men, women and children as pigs, lambs and goats, yet our national expression, disclosed in the present cabinet arrangements, would hardly indicate this to be true. It is not so long ago that Michigan passed through a siege of foot and mouth disease, at which time several cases of suspected animals were placed in quarantine in Wayne county. Immediately an embargo was placed on the entire state and the shipment of live stock of all kinds prohibited for a period of thirty days. There is no doubt but that action is quick and prompt and effective under federal control, as was evidenced in this case. But consumptives are still passing up and down our highways, coughing up their sputum, to await a favorable opportunity on pavement or street to be picked up in a whirling cloud of dust and carried into the noses and mouths of innocent victims. . . . Uniform regulation is of as much importance in matters of health, surely, as in railroad control or legal decisions. A department like the one in contemplation could gather accurate data on all questions of health and sanitation throughout the entire country and conditions and causes regarding all diseases could be carefully studied with the end in view that the chief causes of preventable diseases and unnecessary ill health could be established and the information widely distributed."

The Garland (Utah) *Globe* says: "The establishment of a department to carry on a war against the ravages of preventable diseases would be a godsend to the nation. . . . If this bill should fail to become a law the people would be to blame. . . . Let us unite in asking our legislators to vote for the passage of the bill. We have a Department of Agriculture that looks after the lives and health of plants and animals—why not have a national department of health to aid in saving the lives of the people?"

Resolutions on Optometry

The following resolution was adopted at a meeting of the American Ophthalmological Society, May 4:

WHEREAS, The American Ophthalmological Society is strongly opposed to the so-called "optometry" bills, which are now being brought before our state legislatures; and

WHEREAS, This legislation is unnecessary, unwise and involves a lowering of medical standards; and

WHEREAS, There can be no compromise with its advocates from the medical profession.

Resolved, That if opticians must be recognized, it should be as opticians, and not under the new name of "optometrists;" that if there must be recognition, it should be legal only, and not medical, and that the medical profession should not lend its sanction by serving on optometry boards, or by taking "optometry" boards under the supervision of state boards of medical registration.

POSTGRADUATE COURSE FOR COUNTY SOCIETIES

DR. JOHN H. BLACKBURN, DIRECTOR
BOWLING GREEN, KENTUCKY

[The Director will be glad to furnish further information and literature to any county society desiring to take up the course.]

Tenth Month—Second Weekly Meeting

HYSTERIA

ETIOLOGY: Age, sex, race, heredity, neuropathic tendencies in antecedents, emotions, trauma, infections and toxic agents. Association with organic disorders, imitation.

SYMPTOMS: A, Stigmata and, B, accidents of hysteria.

STIGMATA: A. Sensory stigmata, (a) anesthesia, cutaneous anesthesia, perversion of taste and smell, diminished hearing, contracted visual field, dyschromatopsia, amblyopia. Distribution of anesthesia, one-half of body, geometrical areas and islets. Movable anesthetic zones. Condition of reflexes in anesthesia. (b) Hyperesthesia. Neuralgic pains. Sensitive areas, clavus, Brodie's joints, tender breasts, etc. Hystogenic zones. B. Motor stigmata. Retarded movements, inco-ordinate movements, weakened voluntary movements, "Diathesis of contracture." C. Mental stigmata. Amnesia, localized, systematized or total, abpulia, suggestibility, simulation.

ACCIDENTS OF HYSTERIA: A. Convulsive attacks; (a) grand attacks, prodromal stage, epileptoid period, period of clownism, of passional attitudes, of delirium; (b) modified attacks, vertiginous, globus, epileptoid, tetanic, ecstatic, syncopal, somnolent or somnambulic attacks. B. Motor accidents. Paralysis, hemiplegia, monoplegia, ptosis, torticollis. Contractures. Astasia abasia. Rhythmical spasms, tremors, tics. C. Sensory accidents, neuralgias, cephalalgias, pseudomeningitis, irritable spine, pseudoangina. D. Visceral accidents, (a) respiratory, aphonia, cough, noises, etc., dyspnea, hemoptysis, (b) digestive, anorexia, dysphagia, vomiting, tympanites, (c) urinary, polyuria, anuria, frequent urination, variations in constituents, (d) trophic and vasomotor, erythema and vesicular rash, bloody tears and sweats, dermographism, edema. Contractures and muscular atrophy. Hysterical breast. Hysterical fever.

Book Notices

SURGERY OF THE BRAIN AND SPINAL CORD. By Prof. Fedor Krause, M.D., Geh. [illegible]ierender Arzt am Augusta Hospital zu Berlin. [illegible] Herman A. Haubold, M.D., Clinical Professor i[illegible] Hospital and New York University Medical College. Vol. I. Pp. 282, with illustrations. Price, $6.00. New York: Rebman Co.

The first portion of this book is devoted to a brief description of the various methods of opening the cranium and of the instruments used for that purpose. The author manifests a distinct preference for the osteoplastic method by use of the Dahlgren forceps (which is of the type known in this country as Devilbis). Emphasis is placed on the dangers of hemorrhage from various structures, and the compression methods of Haidenhain and Kredel for control of scalp hemorrhage, and of crushing and packing for that from the bone, are given preference. The advantages of different methods of opening the posterior fossæ are discussed.

Following the mechanical procedure of exposing the brain, the decription of the surgery of each of the conditions calling for surgical treatment is fully presented. Chronic leptomeningitis, arachnoid cysts and cysts of the brain of various characters and their causes, are considered in order. Naturally, a considerable space is devoted to tumors. The surgery of brain tumors comprises a large part of the real progress made in brain surgery in the last decade. Greater accuracy in diagnosis, and especially in localization, together with the advantages of extensive exposures have made nearly all regions of the brain accessible and many of the heretofore unapproachable lesions are now removable.

The various forms of tumor and conditions involving the meninges and cortex, including tuberculosis and syphilis, are considered, and then follows a lengthy presentation of the surgery of the base of the brain, including that of the pituitary body and the nerves. The various details of operative procedures and of wound treatment are given in minutiæ, and the various possible complications and their prevention and treatment are fully discussed. The indications for and technic of decompression trephining are satisfactorily presented.

One of the shortest and most practical sections of the work, for the general surgeon, is that devoted to closure of large cranial defects. Cranio-cerebral topography and puncture of the brain and ventricles are also considered, and the last chapter is devoted to a very brief consideration of radiography.

The terse, clear and forceful text is illustrated by many drawings and fairly illumined by numerous colored plates, which accurately portray the appearances presented by the various pathologic processes and the operative measures.

American physicians are to be congratulated on being now able to obtain in translation Krause's justly celebrated monograph, in which has been preserved, as far as possible, the author's peculiarly effective method of expression.

A System of Syphilis. Edited by D'Arcy Power, M.B., F.R.C.S., and J. Keogh Murphy, M.D., M.C., F.R.C.S. In Six Volumes Vol. III. With an Introduction by Sir Jonathan Hutchinson, F.R.S. Cloth. Pp. 267, with illustrations. Price, $13.50. New York: Oxford University Press, 1909.

This volume contains 250 pages. In it Osler and Gibson of Oxford write on "Visceral Syphilis:" Mercier of Charing Cross Hospital, London, on "The Clinical Aspects of General Paralysis:" Castellani of Colombo, on "Yaws:", S. B. Atkinson of the Inner Temple, London, on "Medicolegal Aspects of Syphilis:" E. M. Brockbank, London, on "Syphilis and Life Assurance;" Haldin Davis of Paddington Green Children's Hospital, London, on "Serum Diagnosis of Syphilis." This volume is thus distinctly a British statement of the subjects considered; for all of the writers on syphilis are Britons except Osler, and Osler, to our loss, the British have appropriated.

Osler and Gibson's contribution constitutes a good brief monograph on syphilis of the viscera. It gives a summary of our knowledge of this subject, but we miss the complete consideration of the topics which their importance justifies. The subjects, however, are covered fully, if briefly, and with its abundant references to the literature the monograph makes an admirable beginning point for one desiring to make a full study of any topic embraced within its scope. Its value is greatly enhanced by twenty-four very instructive illustrations, those of microscopic objects being in color and beautifully reproduced. Mercier's article on general paralysis is admirable. It is detailed, logically developed, and forms a most readable brochure on the subject.

A chapter is given to yaws. Yaws is not syphilis, but the consideration of yaws in a system of syphilis is pertinent because of the many close relations between the two diseases. The article is by Castellani, who, by virtue of his large experience with the disease in Ceylon and particularly by virtue of his discovery of the *Spirochæta pertenuis* as the specific organism of yaws, is perhaps of all men the one best entitled to write with authority on the subject. The interest of his article is much increased by a large number of illustrations showing the *Spirochæta pertenuis*, experimental yaws in monkeys, primary lesions of yaws in men, and various stages and types of the later lesions of the disease in men. Aside from its interest as one of the important tropical diseases, yaws has a peculiar interest because of its many resemblances to syphilis and Castellani's article is a welcome addition to the volume.

The article on some medicolegal relations of syphilis and on the one on syphilis and life assurance are good. Brockbank's article in particular on syphilis and life assurance is suggestive. It is full, with copious bibliography, and contains a large mass of important facts bearing on the influence of syphilis on life-expectancy. All of his facts indicate that syphilis is an appreciable shortener of life. The last article in the volume is on serum diagnosis by Haldin Davis. His description of the technic is a clear description of a very complicated subject and the article as a whole is satisfactory and up to date.

Taking this volume at large it is a useful statement of our knowledge of the phases of syphilis of which it treats and it can be fully commended.

The International Medical Annual. A Year-Book of Treatment and Practitioner's Index. Twenty-Eighth Year, 1910. Cloth. Price, $3.50. Pp. 762, with 108 illustrations. New York: E. B. Treat & Co.

This British publication under the editorial supervision of a number of British and American physicians and surgeons corresponds with the year-books published in this country, but is in one volume instead of in separate volumes for various groups of subjects or time of year. The whole field of medicine and surgery is reviewed briefly, more space being given, of course, to the important subjects, and considerable to the newer topics of experimental medicine, with editorial comment, approving or disapproving certain theories, plans of treatment or operative procedures. The book is well illustrated and offers a comprehensive review of the year's work.

Medicolegal

Liability of Employer for Communication of Contagious Disease

The Court of Civil Appeals of Texas says that the case of Mellody vs. Missouri, Kansas and Texas Railway Co., of Texas, 124 S. W. R., 702, was brought to recover damages sustained by the plaintiff through the alleged negligence of the company in permitting one of its section houses to become infected with smallpox, which was communicated to him, destroying his eyesight. That the railway company would be liable for the spread of a contagious disease through the negligence of its servants acting within the scope of their authority, whereby another was injured as the proximate result of such negligence, was not at all questioned.

At the section house referred to, the plaintiff's father, a section foreman, resided with his family, and one Bryers, another section foreman, boarded. Bryers, it appeared, had gone to Palestine at the time there was an epidemic of what was called "black measles" in the city, talked at a distance of some 50 feet through an open window to his wife, who was quarantined, and arranged to take away their child, who was at another house some 50 feet away, obtaining for both himself and child health certificates from the city health officer. While on the train his child went near another one, whose mother said it had fever, and, as she had but recently lost her husband as a result of black measles, she feared the little one was afflicted in the same way. After being advised of this, Bryers did not permit his boy to go near the sick child any more. Some 15 days after he was brought to the section house he was taken sick with what proved to be smallpox, and it was learned that his mother died of smallpox. Two or three days after the boy was taken sick the roadmaster was at the section house, and the circumstances under which the boy was obtained, etc., were explained to him. Under such circumstances, the court does not consider that there was any liability on the part of the company in these cases.

A careful examination of all the testimony utterly failed, it says, to show actionable negligence on the part of either Bryers or the roadmaster in respect to placing or allowing Bryers' child to remain in the section house until its death, and therefore the railway company could not be required to respond in damages for the injuries sustained by the plaintiff on account of the house becoming infected with smallpox by the presence of Bryers' afflicted child, or because said disease may have been communicated to the plaintiff by actual contact with said child. Clearly, Bryers was not acting within the scope of his authority so as to bind the company up to the time of placing his child in the section house, and, in permitting the child to remain therein the short time which elapsed from the time he discovered the child was probably afflicted with smallpox and the time of its death, he could not fairly be charged with a failure to do what an ordinarily prudent person would have done under the circumstances of the situation.

Current Medical Literature

AMERICAN

Titles marked with an asterisk (*) are abstracted below.

Boston Medical and Surgical Journal

May 5

1 *Exophthalmic Goiter. W. H. Robey, Boston.
2 *Recent Advances in Treatment of Exophthalmic Goiter. C. Frothingham, Boston.
3 *Need of Instruction and Experience in Nursing as Part of Medical Education. F. P. Denny, Brookline, Mass.
4 Physiology Versus Anatomy. G. V. N. Dearborn, Cambridge, Mass.

1. **Exophthalmic Goiter.**—Robey advises that the patient should be given first the advantage of medical treatment by whatever methods the physician can suggest and the patient has the means to adopt. The physician should, however, keep in close touch with his patient and should be watchful for

constantly increasing benefit from treatment. He should not allow his patient to grow worse nor to stand still in a condition of invalidism without the advice of an experienced surgical adviser and operator. It is unsafe to allow an exophthalmic goiter with distressing symptoms to continue without improvement because the toxemia sometimes exerts a sudden and alarming influence on the heart. Again, persons with well-developed exophthalmic goiter do not stand ordinary intercurrent infections which would hardly trouble a normal individual.

2. **Treatment of Exophthalmic Goiter.**—Frothingham gives a splendid review of all forms of treatment employed in this disease, and asks for more complete statistics. They should, he says, be classified according to the number of years since treatment was instituted. The same authors should compare simple medical treatment with that plus the special forms of treatment, such as operation, serum, etc.

3. ***Instruction in Nursing as Part of Medical Education.***—Attention is called by Denny to the importance of nursing in therapeutics, because ignorance of nursing renders the physician's work less effective. He says that physicians need to have personal experience in nursing in order to prescribe treatment intelligently. His plan is as follows: Experience in nursing could be given men medical students in the male wards of a hospital. The students would do the nursing in the wards, under very careful and close supervision, the expense of the supervision being borne by the students' fees. The discipline should be very strict, military in character and good conduct and good work in the wards would be essential for a medical degree. As few patients as possible should be assigned to each student, so that the service rendered would be individual and personal. The students should be made to feel that they are responsible for the comfort of their patients. A nursing service of at least a month, preferably two months, should be required of each student. A part of the service should include night duty, as conditions are very different at night from the patient's point of view and a physician's knowledge of sickness is incomplete unless he has spent a number of nights at a patient's bedside. Combined with the experience in nursing there should be instruction in the various therapeutic measures which a nurse carries out. It could probably be arranged that most of the students should do their nursing during the summer, just as the engineering students have their "field work" at that time. During his nursing service the student will get closer to his patients than he ever has before or ever will again. Pictures of disease, expressions, posture, types of respiration, knowledge which cannot be obtained from books or lectures become impressed on the student's mind in a way that years of clinics would not do. For training in practical therapeutics, there is nothing in the present course to compare with it. Students will become familiar with the appearance, smell, taste, mode of administration and action of drugs. In no other way can the student so well learn the wealth of simple measures, which in the hands of an intelligent nurse, can be of the greatest comfort; for example, moist and dry heat, cold compresses, ice bags, packs, baths, rubbing, counter-irritants, etc. As a means of learning practical dietetics, this experience would have no equal.

13 Norway for Neurasthenia. C. E. Nammack, New York.
14 Serodiagnosis of Syphilis. V. C. Pedersen, New York.
15 Heredity as a Factor in the Etiology of Tuberculosis. E. L. *Shurley, Detroit.*
16 Interesting Points in Gastrointestinal Surgery. T. C. Witherspoon, Butte, Mont.
17 Fibroid Tumors *Complicating Pregnancy.* E. G. Torrance, Birmingham, Ala.
18 *Where Shall the Pharmacopeia Draw the Line of Demarcation? S. S. Cohen, Philadelphia.

12. Abstracted in The Journal, Oct. 23, 1909, p. 1426.

18. **Revision of Pharmacopeia.**—The Pharmacopeia, says Cohen, is a book of pharmacal standards and neither an advisory nor a minatory work on therapeutics. Admission or rejection should depend on the voice of the whole profession, and not on the voice of teachers or leaders only, whether pharmacologists, clinicians or therapeutists. Many preparations of one drug are permissible, when desired by physicians in general. Many drugs of similar action are permissible and even necessary. Active principles should not displace the crude drug and galenical preparations, unless physicians in general all agree that the active principle is the only necessary or desirable preparation. Monopolization by patent or trademark should not exclude a drug otherwise proper to be admitted. *In the* case of *trademarked names legal advice* should be taken as to the best method of procedure. In the case of process patents and product patents, the effort should be made to use pharmacopeial control and standardization to the mitigation of the evils of high price and uncertainty of product possible under the present bad system. A determined effort should be made to modify the laws of the United States so that in the case of medicines, processes only, and not products, can be patented. Trademarks *can only* be manufacturers' brands, and hence the common name of a medicine cannot be used as such. If this is not good law at *present, it should be made* such by statute.

26. **Herniotomy in Inguinal Hernia.**—The simplest and most satisfactory way of treating inguinal hernia in children, according to Judd, is by operation, and the chief indication for performing it is the trouble and consequent anxiety to the mother in caring for the child in this condition. Herniotomy, he says, is the only safe method of treating inguinal hernias in adults. The operation can be done with much better satisfaction and more safety in old people than was formerly believed.

29. **The Baby-Tent Idea.**—The equipment of the tents used in Chicago consists of a hospital tent about 12 by 16 feet, with a double roof, board floor and sides, and screen sides above the chair rail. Each contains 8 iron beds, a hammock, electric lights, 2 electric fans and a telephone. There is also a receiving tent, about the same size, for examining, bathing and temporary care of the baby. Milk-commission milk has been used almost exclusively, as a milk depot was maintained at each tent. The tents are opened about July 1 and closed about September 15. The tents are kept open nights and Sundays only in extreme emergency of either very sick patients, or severely hot weather, to prevent the usual "blue Monday," for it was noted Monday was the worst day of the week. A visiting nurse is in charge of each tent, with one or two assistants. When the work justifies, an intern spends all day at the tent. Every day some physician visits the tent. The arrangements are such that each physician visits a tent twice a week. Only patients under about 2 years of age are received, as those older could not be kept in the beds. Only babies of the poor are taken. When it can be determined through the visiting nurse of the district that the parents are able to pay they are referred to their family physician. A large proportion of these little sufferers are brought in or sent in by the district visiting nurse. When patients fail to return they are investigated by the visiting nurse.

56 *Protein Metabolism in Pneumonia. C. G. L. Wolf and A. Lambert, New York.

50. **Sexual Forms of Malarial Plasmodia.**—From what is said by Craig regarding the action of quinin on the malarial gametes it is evident that if we thoroughly treat our malarial patients during the initial attack of the disease we shall prevent the formation of these bodies, and, therefore, the transmission of the infection to the mosquito. *A great deal of the* malaria prevalent in every malarial locality is directly traceable to improperly treated patients, and the prophylaxis of the disease will be immensely helped by the thorough treatment of every infection. The practice of regarding such infections as cured because the active symptoms have disappeared is a most common and a most pernicious one and one that is responsible for the transmission of a very large proportion of malarial disease. Every malarial patient, he asserts, should be kept on quinin for at least a week or two after the disappearance of symptoms, and should take the drug, in 10-grain doses, once a week for 2 months after the acute attack.

52. **Typhus and Rocky Mountain Spotted Fever.**—The serum of typhus convalescents drawn within a week to 10 days, after the subsidence of fever, Ricketts and Wilder found did not exert any more protective effect against spotted fever than normal serum does. Also, such serums show little or no more agglutinating effect for the bacilli which appear to be associated with spotted fever than do normal serums. A monkey which had been rendered immune to typhus was not immune to spotted fever. These experiments, the authors believe, substantiate the clinical evidence and that obtained by animal inoculations, that spotted fever and typhus fever are not identical, and they seem also to indicate that the organisms of the two diseases are not closely related biologically, whatever the morphologic conditions may be. The fact also that the serum of a disease (typhus) which is roughly similar to spotted fever, has no unusual agglutinating power for the bacilli mentioned, as compared with the high agglutinating power of immune spotted fever serum, supports the contention that this bacillus bears a causal relation to spotted fever.

54. **Scopolamin-Morphin Narcosis in Metabolism.**—Barnes believes that the points brought out by his observations justify the following conclusions:

1. Scopolamin-morphin when given together in sufficient quantity and when leading to a depression of activities cause a decrease in the absolute amounts of nearly all of the normal constitutents of the urine.
2. Scopolamin alone, when it leads to an elevation of activities, causes an increase of such constituents.
3. The increase or decrease affects all constituents about equally.
4. The effect of both drugs together or of the scopolamin alone is shown transiently not more than 12 hours and perhaps less, and on the day following the administration of the drugs the variation is partly counterbalanced by an increase or decrease, as the case may be.
5. Repeated doses of both drugs together over a long *period* of time will lead to a form of tolerance.
6. The influence on metabolism, as indicated by the variations in the urinary secretion, seems due to an indirect and secondary action of the drugs. The retardation of absorption from the alimentary tract is considered the prime cause for the variations found in the urine during these studies.

56. **Protein Metabolism in Pneumonia.**—Wolf and Lambert examined the nitrogen and sulphur metabolism in 19 cases of pneumonia of varying degrees of severity. They found that the cases of milder type show a smaller loss in nitrogen and sulphur than do those of a more severe grade. The daily loss in nitrogen on a diet adequate to protect a resting individual from nitrogen loss may be from 20 to 25 gm. The relative desamidating capacity, as shown by the ratio of urea nitrogen to total nitrogen, is comparable to that of a normal subject. The capacity for the oxidation of the cystin group, as exhibited by the ration of total sulphate sulphur, is quite as high, if not higher than normal. During the period of hyperpyrexia excessive amounts of creatinin are eliminated. This is followed during convalescence by a subnormal excretion of creatinin. This is taken to indicate the endeavor on the part of the organism to repair the losses sustained during the height of the toxemia.

In the severe cases of pneumonia large amounts of creatin are also excreted. This is seen particularly during the time of greatest nitrogen loss. During convalescence the creatin disappears from the urine. In some of the lethal cases the amount of creatin excreted on the day terminating the illness is as high as the amount of creatinin excreted. During hyperpyrexia, especially in cases severely toxic in type, unusually high amounts of undetermined nitrogen are excreted. In some cases over 5 gm. of nitrogen derived from uninvestigated substances are found in the urine. The nitrogen is not derived from albumoses, as the search for these substances revealed quantities which in no way could account for the large amount of rest nitrogen. The sulphur excretion runs more or less parallel with that of the nitrogen; but it appears in some of the cases that the catabolism of proteins rich in sulphur is not so marked as those in which the content of sulphur is small. On the other hand, cases progressing unfavorably seem to show an excessive destruction of proteins containing much sulphur. This is made out from the increased ratio of total sulphur to total nitrogen.

70. Lepra Bacillus in the Circulating Blood.—After satisfying himself of the diagnostic value of Rosenberger's method of demonstrating the tubercle bacillus in the circulating blood, Crow began an examination of the blood of the patients in the leper colony here in Guam. The technic used is practically that of Rosenberger. Sixteen cases were examined. In 15 the blood contained a bacillus which morphologically and in staining reactions is identical with the lepra bacillus. In some cases only a few were found and then only after prolonged search; in other cases they were quite numerous. They occurred singly and in groups with varying frequency, and did not appear within leucocytes as often as did the tubercle bacillus; many were beaded. In almost every case some of the organisms, but not all, showed the long, slender, spindle-shaped outline characteristic of those found in the nasal discharges and in leprous nodules. The negative case shows clinical evidence of the disease.

103. Results Following Fracture of Femur.—Five years ago a well-grown, healthy girl, aged 8 years, was thrown from a horse and suffered a fracture of the left femur near the junction of the middle and upper thirds of the shaft of that bone. It being impossible to adjust the fragments satisfactorily, and there apparently being no union at the end of two weeks, the fractured bone was set by an open operation. The operation wound healed under the first dressing. A pressure sore developed on the heel and another on the dorsum of the foot of the injured limb as a result of the traction. About two months after the operation keloids began to develop in the scars of the pressure sores and the operation wound. At that time the limbs were of the same length as measured by the operating surgeon and the consulting orthopedic surgeon. But after a year it was found that the fractured limb was longer than the other. Two and one half years after the accident, the limb measured an inch longer than the other. Five years after the accident the limb measured two and one-quarters inches more than the uninjured limb. The girl is large, well and active, and, except for the elevation on the shoe of the uninjured side, is unconscious of her disability. In this case there was never any evidence of any injury at any of the epiphyseal junctions; and the appearance of the femur in the *x*-ray picture appears to be conclusive evidence that the increased growth has taken place in the shaft of the bone at the point where it was broken.

The other patient was a boy of average height and slender build, 14 years old. On Nov. 27, 1908, while playing foot-ball he sustained a fracture of the right femur in the upper part of the shaft. Five and one-half weeks after the accident, union appeared to be firm, but the thigh was bowed outward and forward in its upper part, and the limb was 2¼ inches short. Six weeks after the accident Ridlon applied his stretching machine, refractured the femur, made the limb straight, and put it up in full normal abduction, extending from the plaster boot a spica well up on to the ribs. After 2 or 3 days the patient complaining of his heel, a hole was cut and a blister found which ultimately became a pressure sore. There being complaints of the dorsum of the foot, the plaster boot was soon removed. From time to time the plaster spica was shortened at the top and at the bottom until the knee was free, also the ribs on the right side. After 6 weeks the boy was allowed up on crutches, and encouraged to bear some weight on the limb, but it was 12 or 14 weeks before he could walk without his crutches and without pain or weakness. Sixteen weeks after the operation, and 22 weeks after the accident, the splint was removed. The limb was straight and measured ¾ inch less than the other, the gain in length having been 1½ inches. The *x*-ray picture made at this time shows that the lengthening resulted mainly, perhaps wholly, from the pulling downward of the lower fragment. Instead of overlapping the upper fragment 2 inches or more it overlaps it a half-inch or less. Although the *x*-ray picture shows great deformity still present in the bone, the limb as a whole is straight, and the long period of full abduction more than compensates for the ¾ inch of real shortening, and the limb is still practically so long as to be in his way when walking without an elevation to the shoe of the uninjured leg. The results in this case demonstrate the usefulness of the stretching machine in fracture of the shaft of the femur, Ridlon says, when it is desired to treat such fractures with a plaster splint.

109 Problem of Finding Employment for Tuberculous Individuals. M. G. Markham, New Haven.

108. **Bacterial Vaccines.**—The 50 cases reported by Fisher occurred in the services of the physicians of the Connecticut Hospital for the Insane and the adjoining city. Fisher prepared vaccines for all of them. They included 18 different conditions and 7 different types of bacteria. Of the 50 patients, 34 recovered much more rapidly than would be expected under usual treatment. One left the hospital after one injection; 2 died; both the latter were practically moribund when treatment was begun. The cases included one of appendical abscess; a suppurating sinus of the leg; two cases of metritis, endometritis and pyosalpinx; 1 case each of hay fever; bronchial asthma; abscess of the gall-bladder; pyelonephritis; infection of the hand; 6 cases of *pneumonia; 3 cases of coryza;* 4 cases of acne.

7 *The Minute Structure of the Thyroid. D. C. Watson.

4. **New Method of Treating Acute Phthisis.**—Crowe has found that a prolonged reaction resulting from the use of either human or bovine tuberculin can be cut short by a dose of the other, provided that there has been developed some degree of hypersensitiveness to the form of tuberculin which excites the reaction. A start is made by an inoculation of 1/100,000 milligram of T. R. (or the bovine tuberculin—P. T. R.—in the most acute cases, as it appears slightly less liable than the former to cause acute reactions). This dose is repeated and gradually increased once in from 7 to 10 days until a definite febrile reaction is provoked, accompanied by signs of an exacerbation in the disease, malaise, etc. The reaction may not appear for 3 or even 6 days after an inoculation, hence the interval between the doses.

This rise of temperature is allowed to continue until it seems to be steady at the higher level or until the physical condition of the patient causes alarm, when a dose of P. T. R., half the quantity of the exciting dose of T. R. (but not as a rule less than 1/100,000 milligram) is inoculated. The next day the temperature may remain up, but the day after, at latest, it will fall, and after a few days there will be found to be a definite improvement in the physical condition of the patient and also in the local lesion. This inhibitory dose is the exception above referred to. It is now advisable to rest for a time, say a fortnight, or until the temperature has again risen, when the same dose of P. T. R. must be repeated and gradually increased, until for a second time a febrile reaction is induced, when it will be found that a dose of T. R. will not have the effect of cutting short the P. T. R. reaction.

Crowe maintains that on general principles autoinoculations should have a greater effect in influencing the course of phthisis for good, than artificial tuberculin; that is, regarding tuberculin merely as an agent which stimulates the system to produce antibodies. But tuberculin itself causes autoinoculation. The power to stop an autoinoculation at will diminishes this danger. By using T. R. and P. T. R. in an alternating fashion, while the patient becomes sensitized to the one form, the power to prevent mischief is vested in the other, and on a continuance of inoculation of that other the inhibitory action is transferred to the former. For a full development of this inhibitory action hypersensibility should be developed, hence small doses should be used because an autoinoculation effect after the first dose or two is not desirable.

5. **Treatment of Exophthalmic Goiter.**—To the 15 cases previously reported Edmunds adds 4; 3 of the patients were benefited by the milk. Few of the first 15 patients could be traced—and only one of these is in good health.

7. **Minute Structure of Thyroid Gland.**—The examination of the thyroid by Watson in a series of wild rats, all apparently healthy, has shown wide variations in the histologic appearances of this gland. The source from which the animals were obtained was noted in all instances. Watson is of the opinion that the effects observed indicate that modifications in structure and function of the thyroid occur in association with different environmental conditions. Diet may have been the chief factor in inducing the modifications of structure. In this connection it is of interest to note that it was observed that the thyroid of all the animals from any one source invariably presented the same general characters.

8. **Surgical Treatment of Glycosuria.**—Robson holds that certain patients with diabetes may be materially benefited, and some even may be cured if the glycosuria be of pancreatic origin; and that a fairly accurate prognosis of the onset of

diabetes may be made by a careful examination of the urine and feces in certain cases at a period long antecedent to the appearance of glycosuria, and that in this early stage the onset of diabetes may be averted by timely surgical treatment. In his review of the subject, he shows that we cannot hope to cure or even materially to relieve, except temporarily, pancreatic diabetes depending on extensive destruction of the gland by organic disease, whether that be dependent on growth or on chronic inflammation, if either class of disease has extensively involved the islands of Langerhans; nor can we hope to benefit that form of inflammation that singles out the cell islets—interacinar pancreatitis. But, unfortunately, by far the greater number of cases of glycosuria due to pancreatitis are dependent on inflammation of the catarrhal type in which the gland is invaded by way of the ducts from varying causes, such as gall-stones, pancreatic calculi, duodenal catarrh (often associated with duodenal ulcer), typhoid fever, etc., and a considerable proportion of these patients, Robson believes, are curable by surgical measures. At a later stage an interstitial inflammation is produced, which may be arrested and decided relief given by surgical means, though the damage already done to the pancreas cannot be repaired. At a still later stage, cirrhosis of the gland takes place, and if the cell cyclets become involved extensively surgical means are quite useless.

The early recognition and treatment of interstitial pancreatitis, or of pancreatic catarrh, by drainage of the bile ducts, and thus indirectly of the pancreatic ducts, and the removal of the cause, whether that be gall-stones, duodenal ulcer or other conditions, may be the means of averting diabetes. In certain diseases of the pancreas, even after the appearance of glycosuria, surgical treatment is well worth considering, as in a number of cases it has led to a complete disappearance of sugar from the urine, and in others to an arrest in the disease causing glycosuria. Every case of diabetes should be considered from its etiologic point of view, seeing that certain cases of glycosuria of pancreatic origin are curable, and in others the progress of the disease may be arrested by suitable surgical methods that can be carried out with very small risk.

10. **Paleogenesis.**—The term "paleogenetic" employed by Hutchinson is applicable to all conditions supposed to be due, wholly or in part, to inheritance from ancestry extremely remote, so much so that in the majority of cases all history of such association has been lost. The possibilities of paleogenesis are not limited by species or genus, but may be recognized in the most distantly related animals. Thus the condition known as the "dappled" skin occurring both in deer and horses Hutchinson now claims for human beings. It is simply a spotted skin in which the spots become visible only under certain conditions. He also holds that we may recognize paleogenetic structural peculiarities in the dappled skin of leucoderma colli, but a similar predisposition is to be traced in xanthelasma palpebrarum, in the common form of leucoderma, and the very curious congenital conditions which have been recognized under the names of linear ichthyosis, ichthyosis herpetiformis, or Biett's bands. The simplest example of paleogenesis is the "linea fusca," which used to be regarded as a symptom attending a first pregnancy, but which obviously is "the abdominal line" conspicuous in many quadrupeds, made visible in most women by the pigment disturbance which often attends pregnancy.

11. **Fecal Vomiting During Anesthesia.**—It is suggested by Buxton that the following method may prove useful in preventing such an occurrence. Lavage may be employed to clean out the stomach and esophagus with boric-acid solution and hot water. The next step is to perform laryngotomy under local analgesia, or even under light anesthesia, but it is essential in the latter case that the laryngeal reflex should remain active, because vomiting or regurgitation may occur while the larynx is being opened and the stomach tube may be expelled, or vomitus travel beside it into the pharynx. As soon as the larynx is opened and a cocain spray used to lessen spasm, chloroform is to be administered through the laryngeal tube to full anesthesia The mouth is opened by a gag as soon as the patient is analgesic, and a full-sized esophageal tube introduced into the stomach. If the preliminary lavage has been carried out by means of a large tube, and if it has not been expelled, the only further step necessary is to pack very carefully both the upper opening of the larynx and the pharynx around the esophageal tube. As soon as this is done, the free end of the esophageal tube must be allowed to drain into a vessel containing a deodorant and antiseptic. It is essential that the tube be introduced and maintained in the stomach, and that the packing round it be tight. The packing of the larynx is done in exactly the same way as that carried out before an excision of the maxilla, when a preliminary laryngotomy is performed. Packing round the esophageal tube is rendered more easy by cocainizing the pharynx, as it is essential that there shall be no leak of fluid around the tube.

38 *Serodiagnosis of Syphilis. (Séro-diagnostic de la syphilis d' après les résultats enregistrés à l'institut Pasteur au cour de l'année 1909). C. Levaditi and A. Latapie.
39 *Pathogenic Treatment of Tabes and Paresis. (Traitement pathogénique des affections nerveuses parasyphilitiques.) A. Sézary.

35. **Local Anesthesia for Major Operations.**—Chaput has performed 37 major operations lately under local anesthesia, including amputation of the breast or arm, resection of the shoulder, hysterectomy and 25 laparotomies. His technic is somewhat similar to the Schleich method, but he uses large amounts of a weak solution of the anesthetic, injected with large syringes, thus infiltrating the tissues extensively step by step with the operation. Much of the fluid escapes again as the incision is made.

37. **Disturbances in Development.**—Delbet is convinced that syphilis is responsible for more evil than it generally is credited with. He obtained a positive Wassermann reaction in 7 children with a congenital affection of the nervous system, Little's syndrome, contractures, etc., although there was

nothing otherwise to suggest syphilis. The reaction was positive also in a case of cleft palate and one of diffuse angioma.

38. **The Wassermann Reaction at the Paris Pasteur Institute.**—This article tabulates the results of the Wassermann test applied to 821 persons during 1909. The findings were positive in 92 per cent. of the patients with syphilis of less than two years' duration, in 63 per cent. of those of over two years, and 0 per cent. in 18 cases in which syphilis could be excluded; they were also positive in 70 per cent. of the cases of paresis and in 60 per cent. of tabes. The method proved valuable for the retrospective diagnosis of syphilis.

39. **Pathogenic Treatment of Syphilitic Nervous Disease.**—Sézary explains tabes and general paresis as the result of an early reaction in the meninges to the syphilitic infection. It does not manifest itself at the time in any way except by a leucocytosis in the cerebrospinal fluid. Given mercurial treatment at this stage it is readily cured, and he consequently advises prompt mercurial treatment when lumbar puncture reveals evidences of the specific irritation of the meninges persisting after subsidence of the superficial manifestations. The inconvenience of the explorative lumbar puncture is far outweighed, he asserts, by the danger from the ignored meningeal trouble which is liable to progress to tabes or general paresis but which it is thus possible to nip in the bud.

44 Experiences witl , Stomach and Intestines. (Radiologie des Digestionstrak in No. 1.

41. **The Misleading Findings with Radioscopy of the Stomach.**—Stiller says that at first he meekly accepted as beyond appeal the dictum of the radiologists that the cylindrical or steer's horn shape of the shadow cast by the bismuth emulsion in the stomach represented the normal shape of the stomach. This finding was entirely at variance with his thousands of examinations of the stomach by other means and with those of physiologists the world around, but the radiologists merely pointed to their radiographs and facts seemed to speak louder than words. But now he raises his voice in protest and describes experimental and clinical research which has demonstrated that the peculiar steer's horn shape is not the normal shape of the stomach but is the specific reaction of the stomach walls to the action of the clinging particles of metal in the emulsion. The shadow cast is instructive as to the effect of bismuth on the stomach, but it throws no light on the shape and behavior of the stomach in the absence of bismuth. The stomach walls contract under the influence of the bismuth quite differently from the contraction with ordinary food. Artificial distention of the stomach with air or gas is, he declares, by far the most reliable means of determining the normal shape of the stomach.

42. **Behavior of the Gastric Mucosa After Exclusion of the Pylorus.**—The history of this operation and experiences with it to date in various clinics are reviewed and also the results of experiments on dogs to show the changes in the gastric mucosa after the operation. It is far preferable to gastroenterostomy alone, the writers conclude, if pylorectomy is impossible for any reason. Cutting the pylorus away from the stomach and suturing each stump to make a blind pouch of it removes the ulcer from the action of the digestive juices, etc., while the excluded stomach mucosa rapidly develops vacuolar degeneration, thus providing conditions, they state, that favor the healing of the ulcer and ward off hemorrhage, perforation and cancerous degeneration later.

43. **Intermittent Spasm of the Stomach as Reflex Neurosis with Gall-Stones.**—Buettner's patient was a man of 38 who had no suspicion of his tendency to cholelithiasis and his recurring gastric spasms had long been supposed to be a primary neurosis. The attacks commenced with severe oppression and pain in the stomach region and the stomach was seen to be distended with gas, but the pulse was regular and not faster than usual and there was no tendency to labored breathing. The attacks sometimes lasted for hours but there was never any vomiting. The motor functioning was also much exaggerated during the attack. The development of jaundice finally led to examination of the stools when it was found that gall-stones could be discovered in the stool sooner or later after each of the spasmodic attacks. If there had been no jaundice the mystery might never have been cleared up as the functional tests showed during the attacks various anomalies which were assumed at first to be the cause instead of the result. The pain in the stomach was so severe that it masked any possible gall-stone colic. He was unable to find any similar case on record in which the well-defined gastric syndrome was exclusively the result of a reflex neurosis, but he thinks that this may occur more frequently, unrecognized. After passing 238 gall-stones his patient seemed to be permanently relieved and has been free from jaundice and from all gastric disturbances to date.

53 Ease and Importance of Direct Visual Inspection of Upper Air Passages. (Direkte Untersuchungsmethoden der oberen Luftwege.) E. Meyer.

46. **The Prowazek Trachoma Bodies in Conjunctivitis and Gonorrhea.**—Heymann has examined the conjunctival secretion from 235 human beings and from 25 animals of 5 different species, including monkeys, but was never able to find the Prowazek bodies except in cases of trachoma and eye affections resembling trachoma, and in conjunctivitis in infants, and he also discovered the bodies in question in 2 cases of urogenital gonorrhea; these patients were the parents of twins each of which had severe conjunctivitis containing numerous gonococci and these bodies. Prowazek has reported similar findings in another family. This throws light on the nature of the bodies, especially as inoculation of monkeys and guinea-pigs with the conjunctival or urogenital secretions containing the bodies induced a conjunctivitis of gonorrheal type at first but later more of a follicular catarrhal form. In the animals thus inoculated the Prowazek bodies were found in large numbers in the conjunctivitis secretions. He found further that inoculation of genital secretions from patients with a history of conjunctivitis suggesting trachoma induced the same effects in the animals as inoculation of secretions containing the Prowazek bodies. [An editorial note on another page of the *Wochenschrift* states that Herzog, who has been making a special study of these bodies at Budapest, now announces that the Prowazek bodies are merely an involution form of the gonococcus.—ED.]

49. **Thirst Fever in Infants.**—Müller reports that fever developed in some infants who were resisting a change of diet and whom he was trying to accustom to the bottle or the breast by starving them to it. He describes two cases in detail, calling attention to the reciprocal relations between the weight and the temperature; whenever the weight showed that the children were suffering from insufficient intake of fluids, the temperature rose, while it declined again when tea was given. He is inclined to regard this thirst fever as the direct result of the concentration of the body juices, an alimentary, or rather negative alimentary fever, analogous to the "salt

fever" observed in infants. These experiences suggest that the custom of compelling a change of food by starving the children to it may have serious consequences; and also that salt fever may occur without any lesion of the intestines. Possibly the reduced elimination of water through lungs and skin may be partly responsible for the higher temperature. Müller refers to Crandell's report in 1899 of similar cases of fever, in which the temperature rose during abstention from fluids. It was first called "starvation fever," but Müller prefers the term "thirst fever."

58. **Changes in the Pulse Curve by Changes in External Pressure.**—Homberger gives the tracings in the case of a man of 50 complaining of dyspnea. The apex beat and heart sounds were not perceptible; the area of dulness was unusually wide. The pressure of the cuff altered the features of the pulse in one arm while the pulse in the other arm showed no such change. Homberger accepts these and similar findings in other cases as sustaining his assumption that the circulation of the blood does not depend on the heart alone but that the task is shared equally by the heart and the blood vessels.

61 Metabolism in Course of Alimentary Decomposition. (Ueber den Stoffwechsel bei der alimentären Dekomposition.) L. F. Meyer.
62 *Orthostatic Albuminuria. F. Götzky.

62. **Orthostatic Albuminuria.**—Götzky has examined for albuminuria 346 children between the ages of 5 and 13. He found that 14.5 per cent. showed signs of orthostatic albuminuria, that is, 189 girls and 157 boys. There did not seem to be any more pronounced tendency to neuropathies among these children than among their mates, although enlarged tonsils or chronic pharyngitis were more frequent among them. He found no trace of pathologic lordosis among a large number of the children, while true lordosis was quite frequent among children free from any tendency to albuminuria. He discusses the diagnosis of orthostatic albuminuria, the favorable prognosis, etc., emphasizing the necessity for prophylaxis as the main point in treatment. The children should be protected against chilling, especially against getting their feet wet. The albuminuria itself should be left untreated. Overexertion should be guarded against but ordinary play and sports in moderation are to be encouraged. Heubner warns against bicycling, horseback riding and rowing as liable to be too violent exercise in such cases.

76 Research on and Application of Radium Emanations. (Demonstrationen zur Emanationstherapie.) S. Loewenthal. (Ungeregelte Verhältnisse bei Bestimmung und Bewertung der Radiumemanation.) E. Weisz.

64. **Banti's Disease.**—Luce gives the details of a typical case and discusses the history and literature of the subject. He is inclined to admit that the disease is similar to true pseudoleucemia and other pathologic processes originating in the spleen. The spleen process may be idiopathic, tuberculous or syphilitic or of other origin. The demonstration of a tuberculous etiology has not yet been made, but such probably exists, similar to the tuberculous form of pseudoleucemia described by Sternberg and the data presented by Fischer, Sabrazès and others in regard to certain forms of pseudoleucemia in which no tubercle bacilli could be discovered in the lymphomas and yet inoculation of animals with lymphoma tissue gave positive results. He thinks it probable that the spleen, serving as a filter for the blood may become injured by any severe infection of the blood or repeated mild infections, and that this may be the origin of the development of the Banti syndrome. The peculiar vulnerability of the lymphatic system in the young explains, he says, the frequency of the Banti syndrome before the age of 30.

65. **Serotherapy of Epidemic Cerebrospinal Meningitis.**—Lateiner reports 26 cases with encouraging results of serotherapy.

71. **Treatment of Narrow Pelvis in the Home.**—The advantages of institutional management of obstetric narrow pelvis are emphasized by von Franqué but he also outlines the measures that should be advised for use by the general practitioner when this is impossible. In regard to perforation he remarks that if any one has conscientious scruples against it he should not attempt obstetric practice. Not until every parturient with a narrow pelvis is delivered in a maternity can this operation be spared.

72. **Active Immunization by Killed Vaccine.**—Knöpfelmacher reports successful subcutaneous injection of vaccine which rendered the individual immune thereafter to ordinary vaccination. This immunity was realized without development of a pustule. He tabulates the findings in 20 cases. The research reported shows that human beings as well as animals can be rendered immune by subcutaneous injection of killed germs. The vaccine was heated to 58 C. 30 minutes to "kill" it.

74. **Serotherapy in Tuberculous Peritonitis: Autodrainage.**—Evler has applied to tuberculous ascites the principle of autodrainage recently introduced in treatment of hydrocephalus. In a patient with recurring ascites from tuberculous peritonitis he found the peritoneum studded with nodules. He separated the recti muscles and sutured the peritoneum in the opening thus made, producing a permanent fistula opening into the subcutaneous tissue. The skin was sutured completely above. The ascites was thus drained away while the diversion of the ascitic fluid induced an autoserotherapy. Improvement was marked from the start; the ascites did not recur and the patient rapidly regained 25 pounds in weight. He was a man of 32 and the peritoneal affection seems to be entirely cured, Evler says, although there is still some cough and the man complains of pains in the chest and back as before the operation.

85 *Adherent Pericardium and Cardiolysis. (Ueber adhäsive Perikardobliteration und Kardiolyse.) K. Schlayer.

78. **Treatment of Diffuse Purulent Peritonitis with 1 Per Cent. Camphorated Oil.**—Hirschel reports 9 additional cases, supplementary to 3 reported in 1907, in which from 100 to 300 gm. of 1 per cent. camphorated oil were introduced into the abdominal cavity and spread over the intestines and walls by the hand wrapped in gauze. A counter incision was then made and small drains inserted at various points and the abdomen closed almost completely. The oil seems to prevent absorption by the peritoneum, while the addition of the camphor has a tonic action. This procedure was not attempted except in the desperate cases, and the recovery of 55 per cent. in the last series confirms the favorable action of the measure. The main benefit is probably mechanical, either by stopping the efferent lymphatics or by clogging the bacteria in the oil, similar to the action of Peruvian balsam in infective wounds. He adds that Hoehne has reported good results in 42 cases with introduction of 30 c.c. of 10 per cent. camphorated oil as a prophylactic measure before extensive gynecologic operations.

81. **Treatment of Iron Splinter in the Crystalline Lens.**—Elschnig reports several cases of splinter of iron in the transparent lens and four in which the splinter had induced cataract. In one in the first group the perforation in the anterior capsule had already closed up entirely but he succeeded in opening the capsule and extracting the foreign body without impairing the transparency of the lens. It has been his experience that the cataract from an iron splinter is not hard, as generally supposed, and that up to the age of 40 the foreign body may be successfully extracted.

82. **Serotherapy of Tetanus.**—Wiedemann injected in a child with threatening traumatic tetanus about 35 c.c. of serum from 100 c.c. of blood taken from a healthy boy of 14, who two years before had recovered from very severe tetanus. This serotherapy was supplemented by antitetanic serum. The patient promptly recovered and the sudden improvement after the human serum had been injected seems to indicate, he thinks, that it had special efficacy. There have been 3 cases in Wiedemann's district in the last thirty years in which persons just after death from tetanus made sudden movements, the convulsive contraction thus being arrested by beginning decomposition which evidently nullified the action of the tetanus toxin. This suggests that possibly blood serum taken from a tetanus patient (or possibly from a healthy person) after being left a few hours outside of the body, might prove effectual in treatment of tetanus; the condition of the serum then would approximate that directly after death from tetanus.

85. **Adherent Pericardium and Cardiolysis.**—Schlayer knows of only 9 cases in which Brauer's technic of cardiolysis has been applied outside the Tübingen clinic where the operation has been done also in 3 cases, all in the year 1906. The results in these 3 cases are not very encouraging; the operation was followed by sudden paralysis of the heart in one case and no benefit was observed in the second and but transient in the third. He analyzes 12 cases of polyserositis at the clinic with or without weakness of the heart, his final conclusions being that the indications for operative treatment of adherent pericardium depend more on the general tendency to polyserositis than on the involvement of the heart. When the polyserositis is extensive and progressive, little benefit can be anticipated from cardiolysis. In one of his cases a simple laparotomy was followed by retrogression of the main disturbances, the ascites no longer recurring. He adds that the ultimate outcome in the cases of cardiolysis in the literature has not been reported, although great benefit was derived at once from the operation which released the adherent heart from its extra work in moving the chest wall.

Therapeutische Monatshefte, Berlin

89 Elimination of Bromin [illegible] von anorganischem und [illegible] den Urin nach Einfuhr [illegible] Bermann.

86. **Medical Reprints and the Advertising of Proprietaries.**—Heubner comments with approval on the step taken by the *Therapeutische Monatshefte* in refusing to give manufacturing chemists reprints of articles that have appeared in its columns. The manufacturers have hitherto been using reprints of this kind to distribute as literature on their products. Heubner remarks on the credulity with which physicians are impressed with the alleged virtues of new drugs, saying that they are unable to judge new drugs for themselves as they can judge fakes of other kinds. The true value of the drug, he continues, cannot be estimated from the first few laudatory reports on its action. Any physician giving the drug during this tentative stage should appreciate that he is merely giving it a trial, and should watch its effects with the closest care and in the most critical spirit. The physician under these circumstances must be strictly impartial, free from any bias in favor of the drug. But the interests of the manufacturing chemists are all against this impartial study of a new drug. They want to push the drug into prominence and general use at once, and seek by every means to influence the physician's mind. The suggestive name, the way the preparation is put up, the profuse advertising, the alluring prospectus and distribution of free samples—all combine to arouse interest in the drug. Medical men are not so readily influenced by suggestions from patients and the general public, but they are swayed by what other physicians have to say in regard to a new drug. Hence it has long been the custom for pharmaceutic firms to send with their advertising matter reprints giving a favorable opinion on a new drug. Heubner remarks that it has happened that such articles have been written to order. But, as a rule, he continues, they are the honest expression of the authors' opinion. They can only rejoice that wide circles are thus enabled to benefit by the fruit of their labors. The business end of the medical journal profits by it, and the editorial department has become habituated to regard the custom as a matter of course. Heubner asserts, however, that the custom is not the expression of a healthy interrelation between the medical profession, the medical press and the manufacturing chemists. Logical as it may seem to post physicians in regard to the qualities of new drugs, the impression produced by this custom is a false one. It leads to exclusively favorable impressions as it is manifest that only articles containing a favorable verdict on the drug are distributed by the manufacturers. Critical or denunciatory articles are not included in the literature sent out. The information which the physician receives from the manufacturers by means of the reprints is thus one-sided and false. Not only do the contents of the reprints serve to sustain the claims made for new drugs but the names of well-known writers and, with unknown names, the prestige of the medical journal from which the reprint is taken—all help in the advertising campaign. It is thus evident that by supplying reprints to manufacturing firms, authors and editors, consciously or unconsciously, Heubner says, are working in the interests of the commercial houses, while they are working against the interests of physicians seeking to obtain an unprejudiced, objective impression of the new drug. A journal which strives to keep its readers informed in the most comprehensive, non-partisan manner on the special field of science to which it is devoted annuls the ideal uses which it cherishes by giving to outsiders a selection from its articles and permitting their distribution in the form of reprints outside the sphere of its responsibility. The physician trusting to the guidance of the journal is thus led astray. Heubner thus

regards it as impossible for a high-class medical journal to continue this custom of supplying reprints to commercial firms. He adds that it must gradually penetrate deeper into the consciousness of medical men that the present-day influence of pharmaceutical industry on medico-therapeutic thought and action is in many ways more powerful than conducive to the interests of the sick and of science. A reduction of this influence will rather promote than check true progress in therapeutics.

87. **Treatment of Chronic Intestinal Catarrh with Hot Gelatin.**—The large intestine is favorably influenced in catarrhal conditions by injection of a very hot solution of gelatin, says von Aldor. He reports 7 cases in detail in which this treatment was followed by a complete cure of severe chronic catarrh of the large intestine, with diarrhea, which had resisted all other measures. The sphincter and a short distance above are extremely sensitive to heat, and consequently the solution is injected through a tube about 5 inches long, with the patient reclining on the left side. From 40 to 80 c.c. (1 or 2 ounces) of a 10 per cent. solution of gelatin dissolved in water at a temperature of 45 or 52 C. (113 to 125 F.) are injected. The patient lies still for two hours afterward with heat applied to the abdomen; von Aldor has always used for the solvent water Carlsbad sprudel thermal water, as he practices at Carlsbad. Gelatin is a valuable food in gastrointestinal disturbances with intolerance of meat, etc., and it has a local soothing action on inflamed mucosa, while the heat induces a healing hyperemia; the lime content may have also a favorable influence on the local repair. It is further possible, he thinks, that the gelatin may check the secretion by the intestine walls of the readily putrefying fluid to which Schmidt ascribes diarrhea. This assumption is sustained by the prompt arrest of diarrhea and rapid transformation of a strongly positive into a negative response to the fermentation test. In the cases reported the course of daily injections lasted from 18 to 28 days; in the one case with complicating cholecystitis he alternated the gelatin with simple hot thermal water injections. Michaelis has applied hot gelatin injections to arrest typhoid hemorrhage and found them entirely harmless. Weil and two other French writers have reported that gelatin by the mouth and subcutaneously proved more effectual than bismuth and tannin in the diarrhea of infants.

94 *Special [illegible] cers. (Bericht über das erste Halbj[illegible] zur Behandlung von Unterschenkelgeschwüren.) R. L. Grünfeld.

90. **Treatment of Pulmonary Tuberculosis with Artificially Induced Pneumothorax.**—Baer and Kraus give an illustrated description of the technic applied to induce therapeutic immobilization of the lung in 6 cases. The results showed that this method of treatment may prove successful in a certain class of severe cases in which the physician is otherwise disarmed.

94. **Treatment of Leg Ulcer.**—Grünfeld describes the experiences at the special leg ulcer dispensary opened six months ago by the Vienna Krankenkassen exclusively for treatment of this class of patients. In the majority of cases a zinc oxid stiff dressing was applied in the form of Unna's "Zinkleim." This is a mixture of 75 parts white gelatin dissolved in 250 parts boiling water with 75 parts zinc oxid and 125 parts glycerin.

April 11, No. 15, pp. 393-420

104 Seroreaction in the Healthy to the Colon and Typhoid Group of Bacteria. S. P. Tria.
105 Operative Treatment of Stab Wounds of the Lungs: *Two* Cases. (Cura delle ferite penetranti del torace con lesione polmonare.) A. Fontana.
106 Case of Primary Sarcoma of the Tongue, *Supposed Thirty-second* on Record. (Sarcoma della lingua.) G. Serafini.

101. **Effect on the Blood of Long-Continued Quinin Prophylaxis.**—De Sandro reports research on dogs given 40 c.c. of quinin for each 70 kilograms of weight, the administration being kept up for from 2 to 4 months. None of the properties of the blood serum seemed to be altered, neither the color, transparency, toxicity, freezing point, proportion of chlorids, sulphates, nitrogen, ash, etc., showed any modification. The only change detected was finally a slight increase in the specific gravity and of the quantity of organic elements so that the dry residuum rose from 0.239 to 0.664 per cent. by the close of the fourth month.

Hygiea, Stockholm

February, LXXII, No. 2, pp. 97-224

107 Ovarian-Tubal Pregnancy. (Ett ovanligt fall af extrauteringraviditet.) A. O. Lindfors and T. J. *Hellman.*
108 *Five Cases of Latent Stenosis of the Pylorus. R. Dahl.

Supplement to Vol. LXXI, pp. 1378-1406

109 *Conclusion of Monograph on Tuberculin Diagnosis of Pulmonary Tuberculosis. (Om Koch's gamla tuberkulin vid kronisk lungtuberkulos ur *praktisk-diagnostisk* synpunkt enligt nyare erfarenhet.) J. *Tillman.*

108. **Latent Stenosis of the Pylorus.**—This condition is liable to be mistaken for a gastric neurosis as the symptoms may all subside after the attack and the patient may feel entirely well during the intervals. The lack of any history of gastric ulcer in some cases is also misleading. The attack of cramp-like pain in the epigastrium resembled the gastric crises of tabes in 2 of Dahl's 5 cases reported in detail. Hyperacidity is the rule for a time at least afterward and some degree of motor insufficiency, but conditions in regard to motor functioning may soon return entirely to normal. The intermittent, periodical character of the attacks and the lack of tenderness in the stomach region during the intervals are characteristic. Oettinger has published a case of the kind entitling it "unrecognized stenosis of the pylorus," but Dahl declares that it is easy to recognize if the above characteristics are borne in mind. The patients have been free from all disturbances since operative treatment, pylorectomy or gastroenterostomy. Three of his patients were 30 or 32 years old, the others were 56 and 70. The attacks had recurred with increasing frequency during from 1 to 9 years before an operation was decided on. In every case, he asserts, cure was instantaneous and complete. One of the younger patients seems to have been cured at the same time of incipient pulmonary tuberculosis.

109. **Tuberculin in Diagnosis of Pulmonary Tuberculosis.**—Tillman's article is accompanied by the tabulated details of 100 cases of chronic pulmonary tuberculosis in all of which the course confirmed the findings of the "old" tuberculin test.

STATE BOARD STATISTICS FOR 1909

THE ANNUAL PRESENTATION OF RESULTS OF STATE BOARD EXAMINATIONS WITH ANALYSES AND DEDUCTIONS

On pages 1740 to 1755 will be found four tables, A, B, C and D, giving in detail the results of the various state medical license examinations held during 1909. Complete reports from Alabama were received for only one of the two examinations held; otherwise our returns are complete.

These tables have been arranged so that, read from left to right, they give the results by colleges, showing how many graduates appeared for examination in each state and whether they passed or failed, as well as the total number examined during the year, the number who passed, the number who failed, the percentage of failures and the number of states in which graduates of each school appeared for examination. Read from above downward, they give the results by states, showing the number registered and rejected from each college, the total number examined, the total number registered, the total number rejected and the percentage of rejections. The fact that the majority of graduates take the license examination in the state in which the college is located is shown by the dark diagonal zone made by the grouping of figures, passing from the left upper to the right lower corner of each table. These tables are worthy of much careful study and many important deductions are possible.

Caution in Forming Conclusions

In making comparisons on the basis of these statistics several factors should be carefully considered. The number examined is important since, if all other conditions are equal, the larger the number of graduates examined, the more accurate is the finding. But other conditions are seldom equal. The number of states in which a school's graduates have been examined is important. The larger this number the more accurate will be the conclusions. Again, the character of the board making the examination and the methods employed are important factors to be considered, since some boards mark severely while others, especially partisan boards, may be very lenient. Finally, in this connection it should be stated that the character of the license examination as usually conducted at the present time is such that graduates of colleges conducted largely by quiz-class methods may easily be successful in passing them. Therefore, the statistics herewith presented should be taken only as part of any investigation of medical schools, although it is an important part.

Graduates of all Years Examined in 1909

Table A shows the results for all candidates who took examinations in 1909 regardless of the years in which they graduated. This shows that altogether 7,287 were examined last year as compared with 7,770 in 1908 and 7,271 in 1907. Of those examined 19.6 per cent. failed, as compared with 21.7 per cent. in 1908, 21.3 per cent. in 1907, and 20.7 per cent. in 1906.

There were 134 of the medical colleges in the United States which had graduates examined. Foreign graduates were examined in 22 states, the total number being 101. The largest number examined in any state was 44 in New York, doubtless because that state has the leading port of immigration. Graduates of Canadian schools were examined in 27 states, more appearing naturally in the border-line states.

Graduates of 1909 Examined During 1909

Table B gives the results for the graduates of 1909 who were examined during the year by state boards and shows that 4,011 or 55 per cent. of all candidates examined during the year graduated in 1909. Educational statistics show that the medical colleges of the United States graduated 4,464 students last year; therefore, about 90 per cent. of all graduates in 1909 took examinations for license during the year. In some of the states graduates in medicine are allowed to serve their hospital internships without first becoming licensed practitioners, which doubtless accounts for some of the remaining 10 per cent. Of those examined 425 or 10.6 per cent. failed. An analysis of this table shows that of all the graduates of 1909 examined, 2,758, or 68.8 per cent., were examined in the states in which the colleges from which they graduated were located. This shows that states which sanction low-grade colleges are not only responsible for the ill-prepared output of such colleges, but are themselves the recipients of the greater portion of such output.

Recent Graduates Examined During 1909

Table C gives the results for graduates of 1905 to 1909 inclusive which were examined during 1909. It includes, therefore, the figures given in Table B. This table is particularly important, since it deals with recent graduates and is, therefore, the fairest basis for comparison between colleges. Any classification of medical colleges from the standpoint of failures at state board examinations should be based on this table. Of all candidates examined in 1909, 5,891 or 80.7 per cent. were recent graduates, and of this number 15.4 per cent. failed, as compared with 19.6 per cent. for all candidates.

Old Practitioners Examined in 1909

Table D is interesting because it shows the results for old practitioners or for those who graduated in 1904 or previously. Of the total number examined in 1909, 958 or 19.3 per cent. were of those who had graduated more than five years previously. This year, of those examined, 288 or 30 per cent. failed, as compared with 15.4 per cent. of failures for recent graduates. This high percentage of failures is probably due chiefly to the long time these candidates have been out of college and to the fact that they are required to take the same examination as recent graduates. Justice to these candidates, most of whom have already been licensed but who for probably good reasons desire to change their locations, is the strongest argument for interstate reciprocity in medical licensure, or for special percentage allowances at the examinations for years of practice. The total number of these candidates will naturally diminish each year as increased reciprocal relations are established, since, as a rule, the states which do not have reciprocal relations with other states (e. g., California, Florida, Washington) examine the largest numbers of old practitioners. A comparison with Table N will be of interest in this connection.

Undergraduates Examined During 1909

Line 138 of Table A shows the number of undergraduates examined in eight states during 1909. Omitting one report from Alabama, for which complete returns were not received, there were 438 non-graduates examined in 1909, of which number 237, or 54.1 per cent., failed. An unusually large number, 153, appeared for examination in Arkansas since it was the last year when non-graduates could appear for the license examination in that state. The same was true in Alabama although unfortunately the complete figures could not be obtained. North Carolina is required by an amendment to its practice act to register non-graduates, who are permitted to practice only in the sparsely settled mountain districts. The open door for these candidates still remains only in Massachusetts, Mississippi and Tennessee, and the percentages of failures in these states this year for non-graduates were respectively, 86.1, 60.0, and 5.0. The largest number registered was 76 in Tennessee.

Study of Totals and Percentages

A study of totals and percentages as compared with previous years is of interest. The totals of those examined show a decrease from last year and the percentage of failures for all candidates is the lowest since 1904.

Total Results

1909	7287	5856	1430	19.6	5891	15.4	958	30.0	438	54.1	1374	7230

Other deductions from the larger tables have been made and are presented in Tables E to N which are worthy of careful study.

Study of Colleges by State Groups

Table E is based on the first four large tables and gives data regarding the group of colleges located in each state. It shows what states are furnishing the largest numbers of physicians and the failure percentages indicate what kind of training these colleges are furnishing, so far as may be judged from the failures of their graduates before state boards. By comparing the percentages of the first column with the other columns it can be seen whether there has been any reduction in failures for graduates of recent years. Of the 34 states having complete medical colleges, 17 furnished 100 or more candidates examined. Of these 17 groups of colleges, 7 had failure percentages of less than 10 per cent.; 7 had failure percentages between 10 and 20, and 3 had over 20 per cent. of failures. The highest failure percentage was obtained by the Mississippi group. Of the states having 100 or more examined, however, the highest failure percentage was obtained by the Tennessee group, which had 31.0 followed by the Missouri group, with 26.3 per cent. Other deductions are given with the table.

Wisconsin	35	20.0	50	22.0	3	33.3	53	22.6	25	24
Totals Ex'd 1909	3947	10.3	5644	14.7	697	26.5	6341	16.2	..	..

This table gives data relating to the group of colleges in each state. For example, it shows that of all the medical schools in Illinois 904 graduates of various years were examined by state boards during 1909, of which number 16 per cent. failed; of the 779 who graduated in recent years (1905 to 1909, inclusive), 13.5 per cent. failed, and of the 125 who graduated previous to 1905, 32 per cent. failed.

The fifth column gives the rank of each state group of colleges according to the number of applicants. The Illinois group of colleges leads, having 904 graduates examined by state boards during 1909, followed by Pennsylvania with 658, Missouri with 575, Tennessee with 551, and New York with 547.

The sixth column gives the rank of each state group of colleges according to the success of the graduates at state board examinations. It is interesting to compare the figures of the last two columns. While the Illinois group ranks first according to the number examined, it ranks sixteenth in the success of its graduates at examinations. While the Missouri group ranks third in the number examined, it ranks as the twenty-sixth in the success of the graduates

Study of Larger Colleges

Table F is also based on the four large tables and gives the results of state board examinations as they affect the 44 largest medical colleges. Although these schools represent less than one-third of the medical schools in the United States they furnish nearly two-thirds of all the candidates for license. This table shows that *the graduation of large classes by a medical college does not prove excellence of teaching* since several colleges having 100 or more examined have very high failure percentages, which holds true even for the graduates of 1909. In fact, the larger the college from the standpoint of the number of students and graduates the more serious is inferior teaching ability, indicated by a high failure percentage. In fairness to the medical student, and in the interests of the public, such schools should greatly strengthen their teaching facilities or reduce the size of their classes.

Results for Larger Colleges

Comparison with Previous Years (Table F).

Year.	Colleges Represented.	Total Examined.	Per Cent. Failed.	Colleges, 100 or More Examined.	Total Examined.	Per Cent. Failed.	Colleges, 50 to 100 Examined.	Total Examined.	Per Cent. Failed.	Colleges, Less than 50 Examined.	Total Examined.	Per Cent. Failed.	Foreign and Undergrads. Examined.	Per Cent. Failed.
1904	149	6241	16.4	14	2271	11.7	28	1817	16.9	107	2153	21.0	794	13.1
1905	153	6111	18.3	14	2350	12.4	37	2543	17.7	102	1518	28.9	759	51.1
1906	146	6938	17.3	16	2504	14.5	31	2381	16.9	*96*	*2043*	*21.3*	*1097*	*42.5*
1907	146	6207	13.8	12	1626	12.7	36	2578	14.7	98	2003	13.6	1064	55.5
1908	137	6491	17.2	19	2596	15.6	26	1825	*15.5*	*92*	*2070*	*20.8*	*1279*	*14.6*
1909	149	6341	16.2	17	2476	16.9	27	1920	12.3	90	1945	19.2	946	42.6

Altogether for these schools 653 or 14.9 per cent. failed, as compared with 19.2 per cent. of failures for the 1,945 candidates from the 90 colleges having less than 50 each examined.

Besides the graduates of the medical colleges of the United States, 946 candidates were examined, made up of foreign college graduates, graduates of miscellaneous colleges and nongraduates, of which number 42.6 per cent. failed.

Results in Home States and Elsewhere

Table G is of much interest because it shows the results for *each college of examinations in the state where the college is* located as compared with the results of examinations in other states where there is no possibility of local influence. Of all recent graduates examined in 1909, 3,347 or about 60 per cent. took their license examinations in the state where the colleges from which they graduated were located. Of this number only 10.6 per cent. failed on the average, whereas, of the 2,297 candidates examined in other states, 20.8 per cent. failed. This would indicate that as a rule the students' chances of passing the license examinations are better if he stays in the college's home state. In this connection it is interesting to note that not a single graduate of any one of the Tennessee colleges failed in the Tennessee examinations although of the graduates of these colleges who were examined in other states the failures varied from 18.5 per cent. to 77.7 per cent. or an average of 45.2. The chances for success at home and elsewhere were equal or nearly so in 6 instances while the graduates' chances were better in other than *the home state* in 12 instances.

TOTAL RESULTS FOR FIVE YEARS

Table H shows, so far as reports were obtainable, the number registered and the number rejected in each state for each of the past five years. A comparison of this table with the statistics in the last educational number of THE JOURNAL (Aug. 14, 1909, p. 546), shows what would be expected, that the states having the largest number of medical graduates examine the largest numbers of physicians. In 1905 several states registered all or the majority of their applicants on the presentation of satisfactory credentials without written examinations. Now only one state, New Mexico, will register candidates on presentation of a diploma, without examination. This table shows only those registered by examination. Another table (M) shows the total registration by all methods.

CLASSIFICATION OF COLLEGES

Tables, I, J, K and L give a classification of the medical colleges of the United States on the basis of the failures of their graduates at state board examinations during the past year. This classification is based on the examination of *recent graduates* as shown in Table C. In forming conclusions, the caution already given should be observed, of noting the number examined, the number of states in which representatives appeared and the character of the boards making the examination. To form a more exact judgment one should compare the percentage of failures received by any college this year with those received in the classifications published in previous years. Careful investigation shows that a college cannot be considered a high-grade medical school merely because its graduates occasionally show a low percentage of failures at state board examinations. The fact is that several poorly equipped and low-standard colleges appear in the first list. On the other hand, some good schools appear in the second list. For the majority of colleges, however, the classification is fairly accurate.

Table I gives a list of 58 colleges which obtained failure percentages below 10 per cent., 21 of which had no failures whatsoever and 40 had only 5 per cent. or less. The failure percentage for the entire group was 4.3. Table J shows 31 colleges whose failure percentages were between 10 and 20 per cent., of which number 19 had percentages below that for the group, which was 14.4. Table K includes 38 colleges having failure percentages of 20 per cent. and above, of which number 25 had above 30 per cent., 12 had above 40 per cent., and 6 had percentages of 50 per cent. or higher. The average percentage for all candidates from this group of colleges was 35.5.

TABLE F.—COLLEGES HAVING 50 OR MORE EXAMINED

TABLE SHOWS TOTAL NUMBER EXAMINED, PERCENTAGE OF FAILURES AND NUMBER OF STATES IN WHICH EACH COLLEGE HAD REPRESENTATIVES

This table is especially interesting, since it gives data relating to the 44 larger medical colleges arranged according to the number of graduates examined. This allows of comparisons between colleges having classes of nearly equal size. This time the University of Louisville Medical Department had the largest number examined, which place was held in 1908 by Jefferson Medical College and in the three previous years by the College of Physicians and Surgeons of Chicago.

Of the 17 colleges having 100 or more examined, only 8 have failure percentages of less than 10, while 5 stand out prominently with large failure percentages of 27.8, 30.7, 35.0, 44.6 and 50.0. This marked difference holds even in respect to recent graduates (of 1905 to 1909, inclusive).

Of the 27 colleges having between 50 and 100 graduates examined, 15 had failure percentages less than 10; 6 had failure percentages between 10 and 20 and 6 had failure percentages above 20, the 3 highest having 28.6, 33.3 and 38.5 per cent.

The average percentage of failures for these larger colleges for graduates of 1904 and previous years, was 27.0; for graduates of 1905 to 1909 inclusive (recent graduates), 13.3; for graduates of 1909, 9.4 and for graduates of all years, 14.9. Of the 44 colleges, 29 obtained failure percentages below the average. Of the 6,849 college graduates examined by state boards in 1909, these larger schools furnished 4,396, or 64.2 per cent.

TABLE G—Comparison of Results in Home States and Elsewhere. Based on Table C.

College	Total Examined.	Results in Home State. Passed.	Results in Home State. Failed.	Results in Home State. Per Cent. Failed.	Results in Other States. Passed.	Results in Other States. Failed.	Results in Other States. Per Cent. Failed.

In this table the number of graduates examined in the state in which the college is located are grouped in one column, while graduates of that college examined in other states are in another column. This shows frequently that the graduates of certain schools have a better chance of passing the examination in the state in which they are located than they have elsewhere. This should always be considered in making comparisons between colleges. A college having an exceedingly low standard, by having all its graduates examined in the home state, may thus show a lower percentage of failures than a college of much higher grade which has graduates examined by several states.

The heavy-faced figures give the results by states. The first column of heavy-faced figures shows the differerences between the percentages of examinations in the home state and the examinations elsewhere. The plus sign indicates that graduates have better chances of success in the state where the college is located; the minus sign indicates that the chances are better elsewhere. The most marked variation this year is seen in the results for the Tennessee colleges.

In Table L have been placed a number of colleges in regard to which data were insufficient to allow of fair comparison.

A comparison of the classification this year with those of previous years shows an increase in the number of colleges having less than 10 per cent. of failures and a decrease in those having above 20 per cent.

CLASSIFICATION OF COLLEGES

Comparison with Previous Years (Tables I, J, K, L)

	Colleges Having Less than 10 Per Cent.	Colleges Having 10 to 20, Per Cent.	Colleges Having Above 20 Per Cent.	Unclassified Colleges.	Total Colleges.

This table gives the number of candidates registered by examination by each state during each of the last five years, as well as the number rejected. The last four columns give the totals for the five years and the percentage rejected by each state. One 1909 report for Alabama was incomplete, so the figures could not be included.

Four states registered over 1,000 candidates by examination, these being Illinois, Massachusetts, New York and Pennsylvania. Over 3,000 were registered in Illinois and New York.

The highest percentage of rejections was 53.9 in Mississippi, followed by Oregon, Arkansas and California, with 46.7, 45.5 and 35.2, respectively. The states marked with an asterisk (*) included non-graduates among those examined, and for that reason would be expected to have higher percentages rejected.

The lowest failure percentages were in Nevada, 2.6; Michigan, 4.0; Ohio, 5.0; Vermont, 7.4 and Wisconsin, 6.9.

Total Registration in 1909

The tables thus far described have referred to candidates registered by examination only. Table M, however, shows the totale number registered in each state, including those registered by examination, by reciprocity, and under various exemption clauses. Above 100 were registered in 28 different states, above 200 in 9 and above 400 in 3, the largest numbers being registered in Illinois with 686, in New York with 616 and in Pennsylvania with 474 and in Tennessee with 311. Nongraduates were registered in eight states, the largest numbers being 76 in Tennessee, 57 in Mississippi and 52 in Arkansas. Altogether 7,230 candidates were licensed during 1909.

Table N gives those registered without examination on presentation of satisfactory credentials, which included a license issued by some other state. This is usually described by the term "reciprocity," which conveys the idea that the state which accepts the license of another must be granted the same courtesy by the state issuing the original license. The term does not well describe this method of registration, however, since some state boards consider it more fair to the physician to accept his credentials, if satisfactory, whether the state board issuing the original license returns the favor or not. Had not reciprocal relations been established by the 33 states shown in the table, 1,167 physicians, the majority of whom have been in practice for many years, would have been compelled to undergo the ordeal of a second trying examination.

In Conclusion

In the publication of these statistics, our endeavor has been to give an absolutely fair presentation of facts, a knowledge of which is always beneficial. Without question this annual presentation of the results of state licensing examinations has had a most helpful influence on medical education and medical licensure in this country. We reiterate our acknowledgements to the state licensing boards whose ready cooperation and complete reports have made the publication of these data possible.

Totals	5046	674	209	1167	131	7230

This table shows the total number registered during 1909 in each state by the various methods. The first column shows the recent graduates registered, the second column, the old practitioners (graduates of 1904 and previous years), the third column the non-graduates, and the fourth column shows the number licensed through reciprocity. It is interesting to note that states which have registered large numbers through reciprocity have examined very few "old practitioners." The chief exception is New York, which has arranged reciprocal relations with only six other states. The fifth column shows those registered without written examination under various exemption clauses. The last column shows the total number of physicians registered in each state during the year. The figures for Alabama are complete here, but one of the two reports could not be included in the other tables, since the list of failures was not sent in.

Total received from each state through reciprocity	1167	2	1	2	1	12	2	1	13	1	10	1	320	46	77	41	30	2	18	25	3	51	35	1	58	53	2	8	29	7	59	7	5	47	5	7	1	7	1	21	4	4	24	26	36	46	2	3	4

* For six candidates, the names of states where original licenses were granted, were not obtained.

This table shows the number of physicians registered by each state through reciprocity during 1909. "Reciprocity" is not the best term to use, however, since some states, Colorado for instance, register candidates who have satisfactory credentials including licenses, regardless as to whether the state issuing the original license reciprocates with those states or not. Taking New York as an example, reading from left to right, the table shows that New York registered a total of 42 applicants through reciprocity during 1909, of which number 7 came from Michigan, 19 from New Jersey, 3 from Ohio and 13 from Vermont. Reading from above downward, the table shows that 59 physicians left New York during 1909 and registered in other states under the reciprocity provision, of which number 13 registered in Colorado, 1 in Connecticut, 1 in [illegible] gan, 28 in New Jersey, 1 in North Carolina, 11 in Ohio and 1 in Vermont. Colorado leads, having registered [illegible] gh reciprocity, followed by Kansas which registered 98, Texas with 95, Iowa with 83 and Wisconsin with [illegible] to note in what states the original licenses were issued. The table shows that of the 1,167 applicants registered [illegible] 320 or 27.4 per cent. obtained their original licenses in Illinois, the states furnishing the three next highest numbe [illegible] 7, New York with 59 and Missouri with 58.

Altogether 1,167 licenses were issued through reciprocity in 1909, an increase of 75 over 1908, 178 over 1907 and 482 over 1906.

Miscellany

The Problem of the Criminal.—The advanced view of the problem of the criminal, and the one which is being accepted by intelligent men, is that he should be returned to the world after his prison term, not a moral and physical wreck, but if possible, healthier in body and mind. In the new penitentiary being built in New York to take the place of the unhealthful and demoralizing Sing Sing, not all the ideas of the modern penologist will be practiced, but the health of the inmates will be considered and the men released will not have the germs of tuberculosis in their systems, as is now the case with many of them. New York is also establishing a colony for the mentally defective on the pavilion system now in use at modern hospitals for the insane and the tuberculous. Some such plan is sure to be followed in future in the imprisonment and reformation of law-breakers. By it the less hardened would be segregated and would issue forth repentant, and most important of all, with some of their self-respect remaining. When justice learns to punish a man without stripping him of all his self-respect, the problem will be a long way toward solution.—*Newark Evening News.*

Infantile Eczema.—Infantile eczema is found in all classes and conditions of society. In one case the child may be poorly nourished and cachectic while in another the baby may be fat and chubby. In the one case the child may be poorly nourished from the lack of a sufficient amount of wholesome diet, while in the other case there may be a lack of proper relation as regard digestion and assimilation.—C. R. Day, in *Journal of the Oklahoma State Medical Association.*

Appendicitis and Cystitis.—When a chronically inflamed appendix is adherent to the bladder, its removal will bring relief, provided that a colon bacillus cystitis has not already developed. In case of the latter event, operation must be supplemented by measures directed against the vesical infection.—C. W. Bonney, in *Therapeutic Gazette.*

New Patents

Recent patents of interest to physicians:

946529. Making durable solutions of peroxid of hydrogen. Joseph Arndts, Paderborn, Germany.
946633. Hair tonic. Conrad Beyer, Cologne-Rodenkirchen, Germany.
947052. Stoppering device for bottles and the like to prevent fraudulent refilling. Lawrence Blew-Jones, Cornhill, London, England.
946853. Sanitary cuspidor. Harry G. Cathcart, Detroit.
946837. Fountain tonic applicator. Cordelia L. Common, Cleveland, Ohio.
946538. Scalp sprayer. Thomas A. De Vilbiss, Toledo, Ohio.
947153. Optical testing instruments. John F. Forth, Syracuse, N. Y.
946637. Physicians' card index. Charles F. A. Hall, Newburyport, Mass.
946940. Capsule filler. August R. Hesske, Philadelphia.
947078. [illegible]ld. Wilhelm Klapproth, Nieder-[illegible] Germany.
947113. [illegible]ort of the foot. Anthony E. Magoris, Binghamton, N. Y.
946972. Massage apparatus. Coleman J. Manning, Medford, Mass.
946556. Thermocauter. John P. Muller, New Rochelle, N. Y.
946648. [illegible] E. Reichelt, Newark, N. J.
946690. [illegible] stove. Franz Szakall, Palota-[illegible] Budapest, Austria-Hungary.
947609. Work-table for bars, soda-fountain-counters, and the like. Julius J. Betzold, St. Louis.
947551. Truss pad or cushion. Daniel O. Fosgate, Chicago.
947382. Surgical instrument. Justus C. Goosmann, Chicago.
947383. Adjustable bed attachment or rest for invalids. Gertrude M. Greaves, South Yarra, Victoria, Australia.
947412. Abdominal belt or support. Arthur B. Kendrick, East Orange, N. J.
947725. Surgical appliance. William C. Yates, Coalinga, Cal.
947726. Fumigating attachment. Ernest L. B. Zimmer, Minneapolis.
948158. Utilizing nitrous gases. Kristian Birkeland, Christiania, Norway.
948005. Massager. Andrew R. Campbell, Saskatoon, Saskatchewan, Canada.
948233. Body brace. Robert F. MacClemmy, New York.
948234. Body-brace. Robert F. MacClemmy, New York.
948153. Vaporizer for medicines. Arthur G. Whitehorne-Cole, Brighton, England.
948305. Hernial truss. John W. Bunker, New York.
948306. Hernial truss. John W. Bunker, New York.
948443. Pasteurizing apparatus. Robert M. Cauffman and W. Best, Centerville, Mich.
948725. Apparatus for purifying liquids or semiliquids. Nat H. Freeman, Boulder, Colo.
948447. Operating table. Elmer E. Helfrich, Oklahoma, Okla.
948627. Rupture appliance. James C. Hogle and A. Meyer, St. Louis.
948456. Surgical clip applier. Abraham Le Witt, Hartford, Conn.
948930. Preparing medicaments. Alfred Meyer, Mulhausen, Germany.
948835. Ammonia condenser. Bruce Walter, Pittsburg, Pa.
948947. Catalytic and making same. Theodore J. Wrampelmeier, Berkeley, Cal.
949055. Apparatus for removing superphosphates from the decomposition chamber. Knut J. Beskow, Helsingborg, Sweden.
949258. Breast pump. Howard V. Brumley, New York.
949414. Nursing attachment. Hugh B. Cunningham, Arnot, Pa.
949623. Steam face-bath. Sanford [illegible] Dalzelle, Beaumont, Tex.
949728. Supporter. Frederick C. [illegible]
949230. Massage apparatus. Mar[illegible]
949708. Package for chemicals. C[illegible] D. C.
949236. Speculum and spatula. Samuel Kaplan and E. Batault, Geneva, Switzerland.
949539. Vaginal syringe, Oscar Katzenberger, Chicago.
949489. Nozzle. James G. Mastin, Chicago.
949302. Instrument for administering powder and other substances. Ludwig J. F. Nicolai, Dresden, Germany.
949716. Supporter. Arthur Quenzer, New York.
949661. Sterilizing apparatus. Alexandra Richter, Leipzig, Germany.
949550. Massage apparatus. John Sabatino, New York.
949093. Sectional form and truss support. George H. Sherwood, Dayton, Ky.
949134. Local anesthetic. Nathan Sulzberger, New York.

SUMMARY OF A TEN YEARS' CAMPAIGN AGAINST HOOKWORM DISEASE IN PORTO RICO

BAILEY K. ASHFORD, M.D.
Major, Medical Corps, U. S. Army
AND
PEDRO GUTIERREZ IGARAVIDEZ, M.D.
Director of the Service of Tropical and Transmissible Diseases of Porto Rico
SAN JUAN, PORTO RICO

For years preceding the occupation of Porto Rico by the United States, the anemia problem had been widely discussed here by writers of all professions, and public opinion concerning this deplorable condition is well expressed by a physician and literateur, who, writing in 1886, remarks:[1]

> To malaria, to the debilitating influence of a diet, limited in quantity and poor in quality, and to diseases produced by detestable hygienic defects, we can attribute the majority of the anemia of the Porto Rican peasant.

The author of the treatise above quoted was one of the first to acknowledge the parasitic cause of this anemia shortly after its announcement. But the public simplified its opinion further in succeeding years, laying more and more stress on the factor of insufficient food.

DEATHS UNDER SPANISH AND AMERICAN RULE

The number of deaths for the last five years of Spanish rule in the island was 130,207, with an average death-rate of 28.9 per thousand of population. Three thousand and sixty-two of these deaths were due to smallpox and yellow fever. The number of deaths for the first five years of American government was 159,312, with an average death-rate of 33.48 per thousand. Practically no deaths occurred after June 30, 1899, from smallpox, and none from yellow fever.

Thus in the ten years of American government, to 1908, the last statistics available, smallpox and yellow fever as factors in the death-rate have disappeared.

This enormous increase in the mortality incident to the first five years of American government is due to several causes:

1. In 1898 the war and change of sovereignty occurred and for several years a rather serious economic crisis was felt. Heavily mortgaged coffee plantations lost the high prices coffee commanded before our occupation, due to the exclusive tariff laws of foreign markets and at that very time (in August, 1899) a terrific hurricane wiped out a large portion of the coffee trees. This practically ruined a great part of the coffee planters. As coffee was the chief industry, and peons worked from hand to mouth on these plantations for a mere pittance, when disaster fell on coffee they were reduced to extreme poverty.

2. The endemic of uncinariasis which from time immemorial had been becoming more and more severe in the years preceding the American occupation, became very fatal in the midst of the privation and misery attendant on these disturbances of commerce and the elements. It seems to us that we have in the fact of poor and insufficient food, exposure, etc., a remarkable illustration of how, when resistance to disease is lowered in the life of a whole population, an endemic disease becomes a veritable scourge.

3. More important is another element, as yet but very incompletely discussed in Reports of the Porto Rico Anemia Commission. It is well-known that when eggs of the uncinaria fall on dry ground a tremendous number fail to develop and in those cases that do reach the larval or infective stage the larvæ promptly die in the absence of water which is essential to their life. Now uncinariasis in Porto Rico is a series of multiple infestations in the barefooted population and this infestation, we believe, is practically always accomplished through the healthy skin. There are certain places in the island where dampness is perennial and this depends largely on shade; hence, coffee plantations are apt to be, in spots, always infested. When, however, the sun shines long enough to dry the ground there is an enormous reduction in the infectivity of the soil in general. Ninety per cent. at least of the Porto Rican peasants in 1899 were worm-carriers and were generally so heavily infected as to be worm-sick. Soil pollution is a custom among them; 80 per cent. or more of the total population are guilty of this practice. From 1890 to 1899 about 15 per cent. of the total deaths were ascribed to "anemia." But in 1898 and 1899 the rains deluged the island at the very time that coffee culture was at its height and the ground was always wet. Hence the infectivity of the soil was immensely intensified and laborers in a weakened state, due to poor food, wretched shelter, etc., added dangerous fresh infestations to those already possessed. The result was a huge mortality immediately following the hurricane of 1899.

The total mortality for the period of seven months ending April 30, 1900, was 23,936, which is at the rate of 42 per thousand *per annum*.

In the months of October, November and December, 1899, the months immediately following the hurricane, the death-rate was 57, 58, and 49 per thousand per annum, respectively.[2] In addition to this the same authority commenting on the figures given states:

> The present rate of 42 per thousand would be reduced to 31 if we could eliminate the cases of anemia. . . . The causes to

---

[1] Al paludismo, á las causas debilitantes de una alimentacion escasa y de mala calidad, y á las enfermedades producidas por un regimen higienico detestable debemos atribuir principalmente la anemia del campesino puertoriqueño.

[2] The above statistics are to be found in the report of the Superior Board of Health of Porto Rico, pp. 97 and 98.

which this condition is due are of such a nature as to affect the poorest people almost alone. It is well known that a large majority of the island's population is composed of peons, who are scattered over every portion of the country, living in unusually poor hovels, and subsisting on the merest apology for food. This is the class in which this large mortality occurs. It cannot be better shown than by comparing the death rate from anemia in the municipalities of San Juan and Ponce, with that in the municipalities of Utuado and Adjuntas. The former may be considered as inhabited by an urban population, while in the latter by far the greater portion is composed of the peon or poor class. Ponce and San Juan show a death-rate from anemia of 5 and 1 per thousand per annum, respectively, while in Utuado and Adjuntas the death rate is 24 and 32 respectively.

In concluding our remarks for the second five-year period let it be understood that the total mortality is even higher, as the first six months of 1900, with an unusually high death-rate, are not included, due to the change from the calendar to the fiscal year system in furnishing statistical data.

In the last two of the first five years of American government, (fiscal year, 1901-2 and 1902-03) the rains were less continuous and the anemia mortality (and consequently the total mortality) fell to its Spanish normal, minus the smallpox and yellow fever factor. In those first five years, in spite of great publicity given the discovery that the cause of the anemia was "hookworm," in spite of a pamphlet descriptive of the disease, issued as a result of that discovery by the Superior Board of Health of the then military government to all physicians, *practicantes,* and municipal governments in December, 1899, no credence was given the announcement; and this was entirely natural. There was apparently abundant proof that the miserable physical condition of the people was due to the concomitant factors of poor food and poverty, and an united people so explained it.

For this reason, of the 11,885 deaths from "anemia" out of 35,781 deaths from all causes in that year, not one single death was attributed to uncinarial anemia.

In the next five years of American government (1903-1904 to 1907-1908 inclusive) a remarkable change takes place. In 1904 the Porto Rico Anemia Commission began its work and it can be sincerely stated that the fall in mortality can be attributed almost entirely to the campaign of these five years against the disease, which more than all else has given a mortality far above what Porto Rico, a naturally healthy country, should have.

This is not to say that other diseases than uncinariasis do not contribute to a mortality, still unfortunately high. They do, but uncinariasis is still, *par excellence,* the reigning disease of Porto Rico.

In these five years 120,595 deaths occurred, a death rate of 23.33 a thousand a year. A summary of total deaths by five-year periods, taken from official records, is as follows:

TABLE 1

First Five Years.		Second Five Years.		Third Five Years.	
1893	21,616	1898	33,614	1903-04	22,694

Average Death Rate Per 1,000	28.9		33.48		23.33

HISTORY OF THE WORK IN PORTO RICO

Now that at last the continent of the United States has awakened to a realization of the baneful presence of hookworm disease within its own borders and a prominent man of means has made possible the beginning of a campaign against this formidable enemy of industrial and agricultural activity, we, the members of the late Porto Rico Anemia Commission, feel it our duty to deliver to the Rockefeller Commission and the medical fraternity at large, a succinct account of the operations of our commission and its successor, "The Anemia Dispensary Service" in the Island of Porto Rico.

On Nov. 24, 1899, Dr. Bailey K. Ashford, of the U. S. Army, found the extremely prevalent and fatal anemia of the Island of Porto Rico to be due to hookworm disease. He was in charge of a large field hospital, in which were gathered the indigent sick of the cyclone of August of the same year, most of whom were pale, dropsical and debilitated. Not being able to make any appreciable effect on this anemia by abundant and rich food, he was convinced that there existed a common morbific cause, not only for the condition of these patients, but also for that of the great mass of anemics he had noted throughout the island.

He examined the blood of 20 patients at random, found eosinophilia a leading characteristic, and thus was led to examine the feces, where eggs were found which tallied in every particular with those described in Manson's "Tropical Hygiene," then issued to army medical officiers.

Not being a zoologist, Dr. Ashford contented himself with giving a full description of the disease,[3] his blood findings and an exposition of the dangers of the worm to the states from an economic standpoint, leaving to Dr. Charles Wardell Stiles, the recognized American authority on animal parasites, the purely zoologic description of the nematode.

Stiles, in 1902, working with Ashford's specimen of hookworms from Porto Rico, and with others from the United States, found subsequently, announced that zoologically the parasites belonged to a new species, *Uncinaria americana,* although later he changed the name to that which now obtains, *Necator americanus.* The new species, interesting from a zoologic standpoint, although the mode of infection, [illegible] morbid anatomy, treatment and prophy[illegible] caused by the old-world and the new-world worms are, so far as we know, precisely similar, became of tremendous importance when Dr. Stiles demonstrated *for the first time* that hookworm disease was crippling the South just as Dr. Ashford had shown it to be the industrial curse of Porto Rico.

In January, 1902, Dr. Ashford after a careful survey of the literature of this disease in the Surgeon General's Library, returned to Porto Rico and immediately began with Dr. Walter W. King of the U. S. Public Health and Marine-Hospital Service, a complete study of 100 cases in the Tricoche Hospital, in Ponce. These cases were reported elsewhere,[4] giving blood-counts, histories and end-results of treatment up to date of publication. In this article it was shown that over 30 per cent. of the deaths in Porto Rico were charged to "anemia," and an earnest appeal was made to combat the disease that was the scourge of fully 90 per cent. of the agricultural laboring classes *in Porto Rico,* a class representing at least 600,000 souls out of a million population.

A strong editorial in *"American Medicine"* shortly after the appearance of this paper, coupled with the publication, through Col. W. C. Gorgas, then Chief Surgeon, Department of the East, of an official letter to the President of the Superior Board of Health of Porto Rico and an address at the annual meeting of the Medical Association of Porto Rico by Dr. Ashford, pointing out the vital necessity for combating the disease, aroused the interest and concern of the Hon. Regis Henri Post, auditor for Porto Rico, and through him of the Governor, Hon. William H. Hunt. The latter recommended strongly the passage of a bill carrying an appropriation of $5,000.00 for the study and treatment of anemia in Porto Rico, which was favorably acted on by the legislature of Porto Rico in February, 1904, Mr. Post introducing the bill in the Executive Council. Drs. Ashford, King and Gutierrez were appointed members of the commission for this purpose, the War and Treasury departments ceding the services of the first two named. The War Department on request of the Surgeon General furnished a complete field hospital and innumerable scientific instruments and books.

[3] New York Med. Jour., April 14, 1900.

[4] Am. Med., Sept. 5 and 12, 1903.

This marks the first era in the work against hookworm in Porto Rico and was the first demonstration of its endemic presence on American soil, an endemic now so painfully evident in the South.

SYSTEMATIC WORK BEGUN

We began with only a handful of friends. The press thought it strange that hunger should be "discovered" to be due to a parasite and based its incredulity on serious economic crises, through which the island was passing and chiefly to the loss of foreign coffee markets. The well-informed and moderately well-informed people, whose circumstances protected them against the disease, as they were well shod, reasoned that as they were well *fed* they were perfectly protected against this "hunger-producing parasite," in contradistinction to the afflicted pale ones who were desperately poor and had to live on bananas alone. In short we had a difficult situation to meet. Had it not been for one saving clause we would have failed. That element was the poor man himself. He was so utterly miserable that he could not be more so and as he had faithfully embraced each and all promises to cure him of what he persistently called his "*enfermedad,*" (illness), in spite of the more refined explanation of his better educated compatriots he gingerly accepted our treatment.

The moment we opened our hospital the sick began to arrive. We had told the Governor we might treat 600 cases, but when considerably more than 600 had been treated in Bayamon in less than one month and a cured patient began to deposit his entire family and that of his neighbors at one morning clinic, it became evident that we had to move to some other town where we were not known, or succumb to force of numbers. We moved to Utuado, said to be the most hungry of all of the Porto Rican municipalities, with a population of 40,000. We rapidly reorganized our work to satisfy the demands we knew would come, and in spite of every care and outside assistance we were again overwhelmed with patients. They came from every barrio of the extensive municipality, afoot, horseback, and in hammocks. As soon as some notorious old anemic who had spent his last cent to buy iron pills would return to his barrio from our hospital cured, the whole barrio would swarm about our ears. On July 4, 1904, two members of the commission were ill and the one remaining handled a clinic of over 700 persons, each one of whom had to have a clinical summary of his case made out, a specimen of his feces examined and a prescription written, an unvarying rule in all the work done here so far. In addition, a prophylactic talk was administered and blood counts were made in the afternoon in special cases. Aside from this clinic, we had a field hospital of from 54 to 66 beds filled with patients registering from 8 to 30 per cent. hemoglobin, each one requiring medication of a special nature to meet special complications and intercurrent diseases of so profound an anemia.

Our plan was to leave Utuado for some other town in a month but we never got away. Certainly this work was none the easier for the two American members of the commission who had to contend with a foreign language, and a dialect at that, and with a people whose customs and modes of life were not well known, even by many educated Porto Ricans; nor was it at all less trying to Dr. Gutierrez who was taking his part in an unpopular work at the expense of his private interests. In five months, our $5,000 was spent and 5,049 cases had been treated, and we withdrew to San Juan to write the report of the work.

FIRST REPORT

This report which, together with those of succeeding years, was published by the insular government contained 234 pages of written matter in Spanish and English, with illustrations. It comprised, (1) a fairly complete history of the disease throughout the world, and of the commission's work in the five months' campaign; (2) a discussion of the parasite, its zoologic description and its life history, together with all possible predisposing causes for the profound anemia observed; the symptomatology, the pathogenesis, morbid anatomy and course, prognosis, and lethality, prophylaxis, diagnosis and treatment. An appendix to this report gives the details of 61 special cases, in which weekly blood records of hemoglobin, counts of red and white blood cells and differential counts of leucocytes are tabled. Also a synopsis of all deaths, of which there were but 27, or a total mortality of 0.49 per cent.

This report fully demonstrated the cause of death from "Porto Rican anemia" and finally relegated the matter of insufficient and improper food to the secondary place of a mere predisposing factor. It demonstrated beyond a reasonable doubt that uncinariasis was contracted through contact of the healthy skin with infested earth, the first practical demonstration on a large scale of Loos' beautifully clear laboratory experiments, and, above all, it convinced the people of Porto Rico that they were dying of a curable disease; that their entire laboring class was threatened with at least semi-invalidism, and that it could be successfully combated with a drug which had been hitherto unjustly accused in Europe of being a dangerous and unjustifiable remedy. The manner in which the Porto Rican people received this report does them fine credit, not at all understood or appreciated by outsiders, and sweeps away all the bitterness of five years of apparent indifference for which they were really largely excusable. From that time to the present this work has been loyally supported by larger and larger appropriations each year, made by the Legislature of Porto Rico.

In the year 1905-1906, we decided to have our central dispensary and field hospital, and administer from this unit as many sub-stations as our meager funds would permit. Recognizing that the highlands of Porto Rico were the most needy, Aibonito, a town in the mountains, was chosen, and around it were grouped in little towns the bulk of the sub-stations. Apart from these surrounding towns we placed one large station in Lares, a mountain town of the West, and one in Utuado, in the center of the island.

In four of our ten stations the town offered to bear all expenses if we would administer the work and furnish the medicines. The physicians volunteered their services. This alone will demonstrate the excellent spirit prevailing.

SECOND REPORT

Our second report contained 176 pages and reports 18,865 cases. It demonstrates that:

1. The keynote of the campaign looking toward an effective reduction of the frequency of the disease must depend on the treatment of all persons infected, on personal direct education of the laboring classes by lectures and pamphlets, and on a complete reformation of the public health service in Porto Rico.
2. Ground-itch is the first sign of infestation, and to avoid it shoes should be worn and earth pollution stopped.
3. The coffee districts of Porto Rico are the most intensely infested of all regions in the island.
4. Five doses of thymol given a week apart are sufficient to practically cure nearly every patient and to reduce the power of infectivity of the patient to the soil about nineteen-twentieths.

In addition a full plan for future work is laid out and it is *brought forcibly home to all that from this time on the extermination of Porto Rican anemia, is largely a matter of money.* Not the least of the labors of this year was the counting of all uncinariæ expelled after each dose of thymol in 40 cases and after each dose of betanaphthol in 30 more. This was most tiresome and disgusting, but a fruitful work, as we established the fact that after even one dose 74.54 per cent. of the parasites were expelled.

On receipt of this report, again the Legislature of Porto Rico trebled their appropriation of the year before and the third year's work began.

At this point Drs. Ashford and King returned to their services and Dr. Pedro Gutierrez Igaravidez took the directorship of the work.

PERMANENT COMMISSION ESTABLISHED

In view of the fact that the Porto Rico Anemia Commission of the previous two years had demonstrated beyond a doubt the extent and curability of uncinariasis, the legislature of 1906 passed a law organizing for the first time a permanent commission for the extermination of uncinariasis in Porto Rico.

Governor Winthrop appointed Dr. Gutierrez Igaravidez as president and Drs. I. Gonzales Martinez of Mayaguez and Dr. F. Sein Sein of Lares as members of that commission on June 25.

This commission, after discussion of the problems before them, in accord with the plans of the previous commission, considered it necessary to continue the work by means of dispensaries as in preceding years, thus offering to every man, woman or child suffering with uncinariasis, a microscopic diagnosis, a free specific for his disease and printed matter and verbal explanation of the endemic, which would tend to disseminate the facts among his neighbors and friends and thus popularize the reform undertaken.

The requests for dispensaries from nearly every town in the island showed the desire of the people that the campaign be made to cover, so far as resources permitted, every particle of ground possible; the commission realized the justice of these requests and decided to establish the largest number of stations feasible.

DISPENSARIES OPENED

As the practical problem outweighed every other consideration in the fight against this disease, both from the standpoint of prevention and cure, the commission directed its efforts rather toward this phase of the question than to the scientific work which more time and money might have made also possible. Each month as soon as they could be organized, dispensaries were opened in some towns, until 35 were found working at the end of the fiscal year, 1906 and 1907. In order to better administer the stations and supply them, the island was divided into three districts, one for each commissioner. The central station was established near San Juan and directed the entire work.

Each commissioner and some of the directors of dispensaries were permitted to place in the municipal hospitals at the expense of the service certain seriously ill anemics, who were unable to return to their homes and who apart from this offered opportunities for clinical research and for the study of the effects of new remedies for the expulsion of the worm.

In the 35 dispensaries in operation in the year 1906-1907, 89,233 persons were treated, of whom 43.09 per cent. were cured. The remainder, for reasons before expressed, could be considered as having been relieved of such an overwhelming number of their parasites as to no longer suffer clinically from the disease. In addition, such patients possessed only a small fraction of their power for infestation of the soil. The mortality was but 0.21 per cent. The records kept of these patients was the same as kept in previous years; *a card of identification corresponding to the serial number of the history card kept at the dispensary was given each patient.*

LITERATURE DISTRIBUTED

Printed circulars were widely distributed, in which the nature of the "anemia" of Porto Rico was made plain, and also the manner of contracting it and the means of avoiding it. These circulars reached the planters and interested them in sending patients to be cured at the dispensaries. In addition to this, each patient on receiving his medicines was issued a colored card with printed instructions as to the manner in which they should be taken and the means that should be adopted to avoid reinfection. In conjunction with the above prophylactic measures the commission wished to try out the effects of sanitary inspectors who would visit the country barrios (or townships), and who would speak in the homes of these people of the campaign that was going on, investigating at the same time the general health conditions prevailing in each home and advising those who had not visited the dispensary to immediately take up the treatment of their curable affection. These inspectors left a card of explanation at the houses and noted under the printed headings of another card the information required of him by the commission. But lack of funds only allowed three such inspectors. These methods brought a greater number of sick to the dispensaries, caused latrines to be constructed, where before there had been none, and would have been even more fruitful of good had enough money been available to employ more inspectors.

SCIENTIFIC STUDIES

Although the cure of the greatest number of sick and the instruction in prophylaxis were the principal objects of the work of this and following years, we note in addition some scientific studies worthy of special mention:

1. The discovery of the presence of *Ankylostoma duodenale* by Dr. Gutierrez in the Central Station at Rio Piedras in the person of a native Porto Rican who had never been out of the island, thus proving the coexistence of the old-world and new-world species in Porto Rico.

2. The trial of Phillips' eucalyptol and chloroform treatment for the expulsion of the worm by Gutierrez. This treatment was not as successful in the hands of the commission as it was reported to have been by its author. The patients thus treated suffered greatly from dizziness, lethargy, somnolence and fainting spells. Some grave cases of collapse occurred, and as many of them refused to continue the treatment by this medication, it was abandoned.

3. The study of tissues recovered from autopsies performed by the first anemia commission in cases of fatal uncinariasis. These tissues were sectioned and stained by Dr. Ashford in Washington and studied there by him, Dr. King, and by the late Major James Carroll and Major F. F. Russell, both of the Army Medical Corps.

4. The study of the influence on the urine of uncinariasis and the anthelmintics used for the expulsion of the parasites. These voluminous notes were compiled and reported by the first commission and are found in the reports for 1906 and 1907. Notes on animal experimentation performed by Gutierrez and Ashford at the close of the last year were compiled, and sections from the human intestines were photographed of the worm *in situ* by Dr. William Gray of the Army Medical Museum.

REPORTS FOR 1907 AND 1908

The report of 1906-1907 contained 206 pages and was illustrated.

The next year, 1907-08, the legislature again appropriated a sum for the continuance of the work and the 35 dispensaries founded in the preceding year were continued, although some were moved to other towns, and 7 more dispensaries were added, making 42 in all, The service in this year followed the plan of the last year, and 81,375 persons were treated with 51.54 per cent. cured, and a mortality of 0.12 per cent.

In 1908 the Legislature did not appropriate any funds for the continuance of the work, so that it was necessary to close all stations June 30, 1908. Nevertheless, surplus medicines on hand permitted many former directors of dispensaries to continue treating applicants, which they did without remuneration from the insular government.

A special session of the legislature was convoked by proclamation of the Governor to consider the irrigation project for the island and the anemia problem, and in September, 1908, the legislature made a modification of the law placing the work of the Commission under the Department of Health, Charities and Corrections as a bureau of that department with the name of Anemia Dispensary Service. The director of this service was Dr. Gutierrez who began in October to organize it.

In November, 1908, after a month's work in organization, the old dispensaries were gradually restored and the total number increased to 59. The number treated this year plus those treated in the five preceding months by voluntary service by the former directors of dispensaries reached 54,725, of whom 41.49 per cent. were cured and 0.08 per cent. died. In addition, 9,159 were treated as patients of former years, making a total of 63,884 treated in 1908-09.

The following table gives a succinct statement of the work to date:

TABLE 2.—SUMMARY OF ANEMIA WORK

Years.	Patients Treated.	Age: Under Ten Years.	Between Ten and Thirty.	Over Thirty.	Not Recorded.
1904-5...	5,490	566	3,138	1,764	22

1907-8..........	472,407	93	56,950.57	
1908-9..........	305,598	46	32,360.91	
Total	1,302,032	426	$154,191.40	.6175

TOTAL NUMBER TREATED

In addition to the 249,688 patients treated up to June 30, 1909, there have been treated, but not yet classified, from that date to Feb. 28, 1910, 22,568 more; hence the sum total to date is 272,256 persons who have received treatment from 1904 to the latter date, by government work alone. It would be impossible to fix the total number who have been treated apart from government work for uncinariasis. This number cannot possibly be less than 30,000. Thus 300,000 is the total number so far treated for uncinariasis in the Island of Porto Rico since March, 1904.

THE WORK OF DR. KING

This is the first time in the history of the Porto Rico Anemia Commission that all its members have not taken an active part in preparing public reports of its labors. Time and distance separate us from the third member, who otherwise would have shared in the preparation of this work. But it is not amiss to note that Dr. Walter W. King was one of its members, planned with us the work it has accomplished and met the difficult situations it has fortunately weathered. Although he does not sign this article with us, his name is intimately associated with every page of its history.

Senile Cataract Often Avoidable.—C. Ziem of Danzig, Germany, presents a number of arguments to sustain his contention that cataract is not the result of encroaching age alone but is due mainly to other factors, most of them avoidable. He includes among these unhygienic, damp dwellings, a damp subsoil as at St. Petersburg and Rotterdam, and dampness from the melting of heavy snows. Chief in importance, however, seem to be chronic purulent nasal affections, and he relates nine cases in which this coincidence was striking, especially as vision improved materially under treatment of the nasal trouble, and particularly when sinusitis was cured. He attributes the improvement to the bettering of the conditions in the circulation in the region and vicinity. His article on the subject is published in the *Archives internat. de Laryngologie, etc.*, 1910, xxix, 397.

A CLINICAL INVESTIGATION ON THE RELATIONSHIP OF TUBERCULOSIS TO CERTAIN DISEASES OF THE EYE*

GEORGE S. DERBY, M.D.
BOSTON

AND

THOMAS H. AYER, M.D.
WESTBORO, MASS.

We wish to present for consideration a summary of the examination of ninety-two cases in which the ocular disease suggested a tuberculous origin. In selecting these patients for investigation our suspicion of tuberculosis rested on the clinical type of the disease process in the eye.

The study was carried out during a period of five months (October, 1908, to February, 1909) in the out-patient clinics of the Carney Hospital and the Massachusetts Charitable Eye and Ear Infirmary, and we are much indebted to the staff of the latter institution for allowing us to make use of their material.

The plan of work was as follows: Having selected our patient, a careful record of the family history, personal history and present illness was made. The cutaneous test was then performed on the upper arm, for which at first we used a 25 per cent. solution of old tuberculin supplied by H. M. Alexander & Co. More recently we have discarded this for the full strength tuberculin as recommended by von Pirquet in his last publications.

In all of the patients a control vaccination was made. The patient was seen after forty-eight hours and, in case of a negative result, watched until the possibility of a reaction was over.

Following the vaccination, our patients were referred to the medical clinic of the Carney or to that of the Massachusetts General Hospital with the request in each instance that special attention should be paid to the question of an active or inactive tuberculosis. We wish to express our obligations to the members of the staffs of those two institutions who aided us in this connection.

In a few instances in which a definite diagnosis was of great importance and no confirmatory signs elsewhere could be obtained, the patient was taken into the hospital and the subcutaneous test applied for the purpose of producing, if possible, a local reaction.

In tabulating our results we have recorded our medical examinations as positive whenever the consultant reported the case as suspicious. As a matter of fact, there are but few cases in our series in which an absolutely definite diagnosis of tuberculosis elsewhere could be made, and those are, first, the ones in which there was a positive local reaction to the subcutaneous injection of tuberculin; and, second, a few cases of tuberculous adenitis or tuberculosis of the larynx and one of lupus of the nose. No bacilli were found in the sputum of any patient, which only serves to emphasize the early stage of the pulmonary process. In these patients the family history was recorded as positive if there was reasonable evidence of a tuberculosis affecting a member of the patient's immediate family.

Our cases may be roughly divided into two groups, in one of which the ocular inflammation was superficial, and one in which the deeper structures of the eye were involved.

GROUP I

The first group is made up of the so-called phlyctenular cases. We have fourteen cases of phlyctenular conjunctivitis with an average age of 14½ years.

In 3 of these (21 per cent.) the family history was positive. Only 1 patient (0.7 per cent.) showed an elevation of temperature. Nine (64 per cent.) gave positive physical signs. In 7 these signs were in the lungs, while 1 had a tuberculous adenitis and 1 a lupus of the nose. The cutaneous reaction was positive in 11 (78.5 per cent.).

The second division of the first group contains the so-called cases of phlyctenular keratitis (keratitis eczematosa, scrofulous keratitis), and we regret to classify them under so unsatisfactory a term; for in but few of them were actual phlyctenules observed. They are rather the cases of recurrent superficial inflammation of the cornea, with or without vascularization, occurring usually in children and young adults of unhealthy appearance. We have 52 such cases, with an average age of 9½ years; the youngest 1 year; the oldest 27. In this group the family history was positive in 13 (25 per cent.). The temperature was elevated in 25 (48 per cent.). There was positive physical findings in 23 (44 per cent.). In 17 of these the lungs were suspicious. Five had a tuberculous adenitis, 1 a tuberculous empyema, 1 a tuberculous larynx, 1 a tuberculous spine. In 48 cases (92.3 per cent.) the cutaneous test was positive.

It may be noted here in this connection that in a series of 43 phlyctenular cases published last year by one of us[1] 88 per cent. of patients reacted to tuberculin, and in the same paper attention was called to 23 similar cases tested subcutaneously by Stock with an exactly similar percentage of positive reactions. Fifty-nine of the 66 cases of this present series gave a positive cutaneous reaction (89 per cent.), a remarkably close approach to the former figures.

GROUP II

Leaving now for the moment the group of superficial inflammations, we have 26 cases in which the deeper ocular structures were involved. These are made up of 6 cases of scleritis, 6 of interstitial keratitis, 4 of uveitis, 7 of sclerokeratitis and 3 of keratoiritis. As a matter of fact all these cases may be placed together, for although they have been classified anatomically according to the location of the chief process, yet usually during the course of the disease neighboring tissues became involved.

Of our 26 patients the youngest was 6 years; the oldest 49; the average age was 26⅓ years. The family history was positive in 5 (19.2 per cent.). The temperture was elevated in 12 (46 per cent.). The physical signs were positive in 18 (69 per cent.). In 15 of these the lungs were reported as "suspicious," while in 3 there was a tuberculous adenitis. The cutaneous reaction was obtained in 24 (92.3 per cent.). It may be of interest to combine the figures of the first group and compare them with those of the second.

[1] Derby, G. S.: The Increasing Importance of Tuberculosis as a Cause of Ocular Disease. The Newer Methods of Diagnosis and the Treatment, Arch. Ophth., 1908, xxxvii, No. 5.

Group I (Superficial Ocular Inflammations) and Group II (Inflammations Involving Deeper Structures of the Eye)

FAMILY HISTORY

Group I: 66 cases. Positive in 16, or 24.2%.
Group II: 26 cases. Positive in 5, or 19.2%.
Whole Series: 92 cases. Positive in 21, or 22.8%.

TEMPERATURE

Group I: 66 cases. Elevated in 26, or 39.3%.
Group II: 26 cases. Elevated in 12, or 46.1%.
Whole Series: 92 cases. Elevated in 38, or 41.3%.

SUSPICIOUS SIGNS OF TUBERCULOSIS

(Lungs, glands, local reaction to subcutaneous test, etc.)
Group I: 66 cases. Positive signs in 32, or 48.5%.
Group II: 26 cases. Positive signs in 18, or 69 %.
Whole series: 92 cases. Positive signs in 50, or 54.3%.

REACTION TO TUBERCULIN

Group I: 66 cases. Positive in 59, or 89.3%.
Group II: 26 cases. Positive in 24, or 92.3%.
Whole series: 92 cases. Positive in 83, or 90.2%.

In fifty cases out of a possible ninety-two there were signs pointing to a tuberculosis outside the eye, and as pertinent here we quote from the paper previously referred to:

> Since at autopsy tubercular lesions, healed or active, are found in from 40 per cent. to 90 per cent. of subjects, it follows that only in a small percentage of cases, most of them of a severe type, is the diagnosis made during life. There are then many mild cases, some of which are not seen by the medical man, and others in which the signs and symptoms are not clear enough to render the diagnosis possible. Most of these patients get well, and only in the event of autopsy is the disease manifest. In a large percentage of cases where it has been possible to make a definite diagnosis of tuberculosis, the disease has been in an advanced stage and cure has been uncertain. This is especially true of pulmonary tuberculosis, in which the finding of bacilli in the sputum clinches the diagnosis, but means advanced disease. I believe the same conditions exist in regard to ocular tuberculosis. Formerly only the hopeless cases, leading to the destruction of the eye, were recognized, while now we are beginning to recognize the milder types which are curable.
>
> If tubercular disease of the eye is as prevalent as my figures tend to show, it will lie in the power of the ophthalmologist to take a more active part in the fight against tuberculosis than he can at present. We see hundreds of these cases in our clinics each year. My small series shows that many have signs pointing to tuberculosis in their lungs or elsewhere. These are the incipient cases that the tuberculosis expert wishes to reach. Even if the patient shows no general signs of the disease himself, he may be the means of directing attention to the whereabouts of an active focus of tuberculosis in the community.

Our present study tends to confirm these views. Furthermore, if we should search in these cases for signs of the so-called scrofulous diathesis we should find them, as many investigators of phlyctenular disease have shown, in a much larger number of patients, 85 to 90 per cent. As time goes on the identity of scrofula with tuberculosis is becoming more widely accepted. As long ago as 1904 Behring stated:

> Candidates for tuberculosis owe their much-discussed predisposition to an infantile infection with tuberculous virus. The practicing physician will before long become convinced that human pulmonary tuberculosis is no more nor less than the final stage of a tuberculous infection dating from infancy, which infection in childhood manifested itself in the signs of a relatively latent scrofulosis.

We believe that for the good of the community, if not for the individuals themselves, these eye patients should be given a thorough physical examination as a routine procedure. We think it likely that the deep and severe tuberculous infection of the eye are often the final stage of a tuberculous infection acquired in childhood and manifested at that time in the form of a phlyctenular process.

It is important that the significance of these forms of ocular disease should be brought to the attention of the opthalmologist and to the medical profession in general.

TUBERCULIN FOR DIAGNOSIS

In our work the use of the subcutaneous test for diagnosis has been found impracticable except in a small portion of the cases. It is impossible in large clinics to obtain the requisite number of hospital beds and it is very difficult to induce the patient to give up a sufficient amount of time for the test. Then, too, the moral effect of a positive reaction with marked general disturbance is often disastrous and has in our experience caused the patient to refuse subsequent tuberculin treatment. Furthermore, the anticipated local reaction may not be obtained. We believe in confining the subcutaneous test to those cases in which the diagnosis can be made in no other way and in which a diagnosis is essential if an intelligent course of treatment is to be prescribed. We have discarded the conjunctival test as being occasionally productive of disastrous results and as being but little more convenient than the cutaneous. We do not believe that there is as yet sufficient evidence of the superiority of the former test as indicating an active tuberculous focus. There can be no doubt that a negative cutaneous test is of far greater importance than a positive one. A positive reaction can add but little to the diagnosis of the ocular disease while as a result of two negative cutaneous tests tuberculosis may, with reasonable probability, be excluded. We have performed the latter test on nearly 200 patients and have never seen harm result from it.

TREATMENT

Although not included in the title of this paper, it may not be amiss to take up the question of treatment.

We reiterate the belief expressed by one of us previously[1] that these patients as a group are best handled by means of the tuberculosis class. In our work we have seriously felt the need of such organizations, and up to within a few months have had to refer our patients for treatment to the classes of other institutions. Three months ago we assisted in establishing such a class at the Carney Hospital for the treatment of all varieties of tuberculosis and in January a class for ocular tuberculosis alone (of which one of us is in charge) was financed by certain generous private individuals and was started at the Massachusetts Charitable Eye and Ear Infirmary. This we believe to be the first of its kind.

Our machinery there consists of an ophthalmologist, an internist, a social worker and a nurse. Patients are referred from the clinics to the class for the investigation necessary to diagnose, and when this is positive and the patient's case is a suitable one for class treatment he is registered as a member. We have a weekly session, but certain seriously affected patients are seen more often and the patients with milder cases may be instructed to report less frequently. Each patient is given a book in which a minute record of his daily life may be recorded. He is weighed, his temperature taken, and, if indicated, a tuberculin injection is given. This is but a part of the treatment, however, for it is most important to reach these patients in their homes and to exercise a strict control over their manner of living. Our treatment differs but little from that of the general tuberculosis class, except that our cases are usually a milder type of disease than the average one seen in the general class. We insist on rest during an active inflammation, and especially if the temperature is elevated during some period of the day, even if the rise be slight. The patients are taught cleanliness and how to get the maximum amount of fresh air. They have the usual antituberculosis diet and forced feeding. They are visited in their homes by our social worker as often as is necessary, and in this way we keep in close touch with them and do not have to depend on their own statements.

The severity and duration of the treatment needed varies markedly with the individual case. Most of the patients in phlyctenular cases soon recover and remain well if they contiue to live in good hygienic surroundings. We have them report every month or two. The deeper processes have been much stubborner and in our hands usually require treatment for many months. As has been observed by many, these cases are all especially liable to recurrences even when the patient's condition becomes robust.

We have a certain amount of money at our disposal to help worthy patients who can not follow out directions on account of lack of means. Those who have not homes where proper treatment may be carried out are referred to various institutions which have facilities for handling tuberculosis. Occasionally we meet a case in which class treatment is not successful. These are referred to the sanatoria; just as in all medical cases each patient must be treated as an individual and the treatment modified to suit his wants.

The paper referred to above[1] stated that the writer (G. S. D.) had been convinced of the value of tuberculin. As the result of further observation we wish to modify this statement. In the classes referred to tuberculin is used in all severer inflammations. As a rule the phlyctenular case does not need it. We believe that, as a rule, our patients do better when tuberculin is used. We employ now a bouillon filtrate obtained from Saranac and begin ordinarily with an initial dose of 0.0001 mg. It has seemed to us that our patients did better and suffered less harm on small and increasing doses rather than when given larger doses for the purpose of stirring up a slight local reaction. We have, however, seen in certain instances a marked improvement follow the diagnostic injection of old tuberculin, and in one instance, a case which had reached a standstill, the patient began to improve again after one or two large doses had been tried; but we have also often seen setbacks result from too large dosage, and therefore we do not believe in it as a routine procedure. We believe that the use of tuberculin should always be second to strict hygienic treatment even if the patient be in apparently good condition, for we know of the great good which may be accomplished in this way alone.

To conclude, allow us to report an interesting and severe case that resisted class treatment and tuberculin but yielded readily after the patient was sent to a sanatorium.

History.—M. M., a man, aged 26, was referred to us for treatment May 5, 1908. Following measles when he was 11 years old he had numerous attacks of ocular inflammation which seriously damaged his sight and kept him out of work. During several of these attacks he was treated as an in-patient in the Massachusetts Charitable Eye and Ear Infirmary. The attacks were so frequent that he was able to work only five months all told out of the last thirty-six.

Examination.—The patient had swollen lids, intense photophobia and lachrymation; both corneæ were covered with old scars and a well-marked pannus. There was no trachoma. V. O. D. and V. O. S. = hand movements. It was necessary to lead the patient. General examination showed a poorly nourished man with the signs of an old pulmonary tuberculosis at the left apex. Cutaneous reaction positive. Temperature elevated. The patient was in a most despondent condition.

Course of Disease.—In conjunction with the Massachusetts General Hospital Tuberculosis Class we took charge of him and a strict antituberculosis regimen was prescribed, with tuberculin injections and appropriate local treatment. The patient was helped financially, as, outside of what his wife could earn cooking, they had no means of support. Although we did everything in our power for him, his improvement was very slow, and at the end of ten weeks we decided to send him to the state sanatorium at Rutland, at which institution he was admitted July 15. Here his improvement was most rapid; the ocular inflammation had subsided at the end of five weeks, and his vision had increased to 10/200 o. u., as much as he had had for some years previously, according to his former hospital record. He left Rutland after seven weeks, having gained 24 pounds and feeling in better condition than ever before in his life. He resumed his work in a golf-ball factory and has not missed a day in the last six months. He reports occasionally for observation and is careful of his method of living.

7 Hereford St., Boston—54 West Main St., Westboro.

ABSTRACT OF DISCUSSION

Dr. W. H. Wilder, *Chicago*: The results that Dr. Derby has obtained accord closely with those which I have had in the cases I have examined. It is astonishing how frequently in cases of phlyctenulosis we will get a positive reaction to tuberculin tests and how frequently in certain other suspicious eye diseases if we make the cutaneous test we will get a positive reaction. So that these results seem to show that, after all, as v. Pirquet has stated, from 70 to 90 per cent. of individuals will react to this delicate cutaneous test. This would help to bear out the statement of the pathologists that, at the age of 60, 999 individuals in 1,000 have tuberculous lesions. Of course, to believe such a statement must require more credulity than some of us possess, because I do not think the pathologists can positively demonstrate the fact. But at any rate there must be a great deal of latent tuberculosis. If we find that so many of our cases of suspicious eye disease will respond to the tuberculin test, can it be made of any great value as a means of diagnosis? Possibly it may be, and it will be the work of the committee which has been appointed to try to determine if there is any possible relation between the lesion in the eye and the severity of the reaction obtained in the test; also whether there is any relationship between the suspected lesion in the eye and tuberculous lesions elsewhere in the body. Possibly the study of a large number of cases may enable us to arrive at some definite conclusion. Again, it will be of value in the study of an eye lesion of suspicious character to be able to determine whether or not there is a more or less active tuberculous lesion elsewhere, for it will direct treatment to this condition and will teach the ophthalmologist that he must cooperate with the general practitioner or the physician who is familiar with tuberculosis in the management of such cases. Another interesting and important question is whether it is necessary to have tuberculous foci in the eye itself to account for certain diseased conditions, as many of the Germans hold, or whether it is not possible for toxins originating in a tuberculous lesion elsewhere in the body to excite in the delicate structures of the eye inflammation that would take on the form of iritis, cyclitis, keratitis and others of a suspicious nature. I am inclined to think the day will come when we will have proof that toxic inflammation from tubercle elsewhere in the body may be responsible for many lesions of the eye, the etiology of which is now obscure.

Dr. W. C. Posey, Philadelphia: This paper is further evidence of the tuberculous origin of phlyctenulæ, a question which has been much in dispute during the past decade, while the detection of signs pointing to tuberculosis in fifty of the authors' cases out of a possible ninety-two should impress on us, as they suggest, the importance of a thorough physical examination in this class of cases, not only for the advantage of the individuals themselves, but also for the good of the community at large. An article in the April number of the *Klin. Monatsblätter für Augenheilkunde*, by Cohen, has a similar trend, for of 123 adult patients with phlyctenulæ who were collected from Uhthoff's clinic, 63.4 per cent. were tuberculous. It is of interest to remark in the analysis of this group of cases that the diagnosis of tuberculosis elsewhere in the body was established by the older clinical methods, without the means of modern diagnostic aids, most of the observations having been made prior to their discovery. Of particular significance was the fact that the phlyctenulæ in many of the cases were found to occur in the first stages of tuberculosis, and that in a vast majority of the cases there had not been an earlier inflammation of the eyes during childhood.

Drs. Derby and Ayer have discarded the conjunctival test as being occasionally productive of disastrous results and as being but little more convenient than the cutaneous. This perhaps is the present practice of many clinicians and is being more universally pursued. Considerable difficulty certainly attends the endeavor in many cases of suspected tuberculous disease of the eye to ascertain whether a tuberculous element is actually present or not. Thus, when tuberculin is injected for diagnostic purposes, the local reaction, even in undoubted cases of tuberculosis, is often absent, or at least but transient, and when a general reaction is obtained, without local signs of irritation or inflammation, it frequently seems presumptious to conclude with any degree of certainty that the case is one of tuberculosis of the eye. The observation and study of a large series of cases can alone solve the problem, so that in time the varied forms under which tuberculosis occurs in the eye may be differentiated into definite types.

For some years past, I have endeavored to recognize tuberculosis of the cornea at first hand by simple inspection, and have found after the diagnosis had been controlled by tuberculin tests, that the projection of a tongue-like area of yellowish-white infiltrate from the limbus into the interstitial lamellæ of the cornea toward its center and the occurrence of discrete yellow-white oval areas, which appear caseous and avascular, is very significant of tuberculous keratitis, while I have observed the deposition of small rounded areas resembling drops of cold mutton fat on the posterior surface of the cornea or in the lamellæ of the cornea, secondary to tubercle of the iris and of the deeper parts of the eye.

Dr. Derby's suggestion of a tuberculosis class appears to solve the difficulty which all ophthalmologists must have experienced in treating these individuals purely as ophthalmic patients, for but few ophthalmic hospitals are equipped to care properly for such cases, and the establishment of such classes in all cities seems most desirable.

The fact, now presumably fairly well established, that the occurrence of phlyctenulæ in adults as well as children, indicates a tuberculous infection, should be appreciated not only by ophthalmic surgeons, but by general practitioners as well, both for the suggestion which the appearance of the phlyctenulæ may give of the seat of tuberculosis in the system, as well as for the necessity which arises of treating subjects with this ocular disease as possible sources of tuberculous infection to others.

Dr. G. S. Derby, Boston: We lay very little stress on a positive skin reaction, as so many individuals will show it, but if there are two negative reactions tuberculosis can be excluded with reasonable probability.

Symptoms of Bladder Calculi.—Diurnal urgency, pain in the bladder, pain at the external meatus at the end of micturition and the presence of blood corpuscles in the urine should lead one to examine for stone.—C. W. Bonney, in *Therapeutic Gazette*.

TREATMENT OF HOOKWORM DISEASE*

EDWARD E. LINDEMAN, M.D.
TAMPA, FLA.

It has recently been roughly estimated that there are 2,000,000 people in the United States infected with hookworm disease. Since it is a disease prevalent in the country districts of the sandy soil area of the South, where perhaps more recent literature on the subject has not as yet permeated, I have undertaken a discussion of the treatment of hookworm disease, including some practical points from my own observations, with the hope that this article may reach those parts where this information may be new.

THE PARASITE AND ITS MODE OF ENTRANCE

It might be well first to state briefly the life cycle of the parasite producing this disease. The disease is caused by the *Uncinaria americana* (Stiles) which belongs to the roundworm family *(Strongyloidæ)*. This worm is from 7 to 11 mm. long and 1 mm. in diameter. It inhabits the intestinal tract, principally the lower part of the duodenum, the jejunum, and the upper portion of the ileum, where it attaches itself to the mucosa by its dorsal and ventral lips or suckers. It is also armed with a prominent dorso-median buccal tooth, which is simply a hollow tooth-like spine. With this tooth it pierces the intestinal wall to reach the blood-channels, draws blood into itself for food and injects a toxin through the same opening. It thus produces small hemorrhagic erosions on the intestinal wall. Both male and female worms inhabit the intestinal tract. The female worm is very fertile and lays eggs abundantly. These eggs are cast into the exterior world with the feces. As many as 4,000 worms have been found in one individual, and as many as 2,000,000 ova may be discharged in a single stool. Where proper conditions of soil, climate, moisture and oxygen prevail, these eggs readily hatch into larvæ. The larvæ are exceedingly minute, unseen by the naked eye, and are found in soil, drinking-water and food which may be polluted. The larvæ enter the body mainly through two channels: (1) with ingested food and water; (2) through the skin. It is the latter which is regarded by most authorities as the main avenue of entrance, more frequently the skin of the feet, because of the more ready and intimate exposure of these parts to the polluted soil by people going barefoot during the warm (which is the infective) season. The hands and arms are next in frequency as routes of entrance, but the larvæ may gain entrance through any exposed surface with which they come in contact. The larvæ present in the skin produce an itching sensation accompanied by an inflammatory reaction, and sometimes secondary infection of other microorganisms may take place. This condition is commonly known as ground-itch or dew-itch. The larvæ, having pierced the skin, soon gain entrance to the lymph and blood-channels, through which they are carried to the heart, to reach the capillaries of the lungs. They then pass through the capillary walls into the alveolar spaces; from here they migrate through the bronchioles into the bronchi, and then crawl up the trachea to reach the mouth cavity, after which they are swallowed in ordinary acts of deglutition, eating, drinking, etc., and thereby reach the intestinal tract.

---

* Read before the Florida State Medical Association, April 6, 1910.

TREATMENT BY THYMOL

There is perhaps no drug whose action is more nearly a specific in the treatment of this disease than is thymol. There are, however, a group of cases, and those usually of the more extreme type, that are not relieved by thymol, and among a number of practitioners this drug has fallen somewhat into disrepute, and other drugs, such as betanaphthol and turpentine, have been substituted. The administration of thymol is not without some danger unless certain necessary precautions are observed. Severe intoxications have not infrequently occurred because of the improper administration of the drug by the profession as well as by the laity.

Further, in other instances thymol has been administered in such form as to pass through the intestinal tract *en masse* with no more effect than pellets of lead. For instance, there have been sent to the bacteriologic laboratory of the State Board of Health of Florida a few stone-like masses about the size of a small marble which were obtained from the stools of children suffering with hookworm disease which were regarded as a concomitant pathologic condition with uncinariasis. These on microscopic examination and chemical analysis proved to be pure thymol. It is self-evident that thymol in such form can have little or no theraputic value. Thymol in this case had been given in a pulverized state in ordinary capsules.

There is, too, a group of cases unrelieved in which thymol has been administered in mucilage of acacia, and in which no such masses as above stated are formed. At the Hookworm Conference in Atlanta, Ga., and in Tampa, Fla., to explain these unrelieved cases it was suggested that there must be some idiosyncrasy or a development of an immunity to the drug.

Now, to clear up these elements of doubt and put the treatment on a safe and rational basis, it is necessary to appreciate the following points:

1. The pharmacology of thymol.
2. The object to be desired in the treatment.
3. The best means of obtaining this object with highest therapeutic value, least dosage and least deleterious effects to the individual.

PHARMACOLOGY

Thymol (*Thymus valgaris*, Linné) occurs in common thyme and several other plants and forms large, colorless, translucent rhombic prisms, having an aromatic, thyme-like odor, and a pungent thyme-like taste, with a slight caustic effect on the mucous membrane of the mouth. It melts at 50 centigrade, is soluble 1,100 parts of water and in less than its own weight of ether, alcohol or chloroform, and is soluble in glacial acetic acid, fixed oils and fats.

TOXICOLOGY

The toxic effect of thymol is obtained when absorbed. These toxic effects are similar to those of the phenol series, but of a somewhat milder grade. In fact, thymol is closely related chemically to phenol, differing only in having a methyl and a propyl radical to replace two of the hydrogen atoms in the benzin ring. In poisoning from its use, locally there is a burning sensation in the stomach and slightly caustic effects on the mucous membranes of the intestines, producing intestinal irritation and evacuation of feces, nausea and vomiting. Tremors and convulsions are induced, though rarely, and less intense than those induced by phenol.

Fatty degeneration of the liver, marked congestion and even consolidation of the lungs have been observed. In the milder forms of poisoning together with the local mild caustic effects and burning sensation in the stomach, there are tingling sensations over various parts of the surface of the body, tremors and muscular twitchings, which may go on to convulsions; in fact, the patient may show any of the symptoms resulting from irritation of the anterior cord. In the more extreme cases of poisoning this is soon followed by collapse; while in others the stage of irritability may be missed, owing to the debility of the patient from disease. The debilitated patients making up the greater group of those poisoned, the more frequent picture is that of apathy, collapse, paralysis and shock, in which stage the patient may succumb. In the stimulating stage the respiration and heart-rate are increased. In the stage of collapse there is a slowing of both heart and respiration, the former being due to direct action on the heart musculature.

Thymol has no toxic effects constitutionally unless in solution and absorbed. When absorbed it has absolutely no therapeutic value in the treatment of hookworm disease. The therapeutic value of thymol is confined entirely to its action on the worm in the intestinal tract. The worm is affected by thymol in crystalline form as well as in solution, and while the solution is more toxic to the parasite, the crystalline form is sufficiently toxic to paralyze or kill it, but it accomplishes this only if the individual crystals reach the individual worm; *it is therefore evident that thymol passing through the* intestinal tract *en masse* can come in contact with relatively very few worms. The more widely disseminated the individual crystals the more worms will they reach and the higher the therapeutic value.

METHOD OF ADMINISTRATION

Thymol has very strong adhesive properties, and when placed in capsules, whether loosely or tightly packed, readily forms a conglomerate, stone-like mass. I was therefore led to experiment with thymol in order to determine how it might be administered to permit the widest dissemination of its crystals. The drug was packed in capsules with different degrees of compactness, in finely and coarsely pulverized states. Acidulated tap water was used as the solvent, and slight stirring was done to imitate gastric conditions. It was found that while some thymol went into suspension, much of it formed solid lumps. Those packed loosely and in a finely pulverized state broke into several lumps, about one-quarter of the amount going into fine suspension; those packed loosely and in a coarser state were a little better divided and suspended; those packed tightly, whether fine or coarse, remained in almost the same state. Cachets were then tried in a similar manner, with perhaps a little better result, but not quite all that was desired. It occurred to me that better results might be obtained by triturating the crystals with a readily soluble substance and packing them loosely in cachets, so that when the drug reached the gastric menstruum the soluble intercrystalline substance would go into solution leaving the thymol in a finely divided and widely disseminated state of suspension. Equal parts of milk-sugar was used as the triturating vehicle. The results were all that could be desired.

Now while the form of administration, as is self-evident, must modify the dosage required, and this fact in a measure explains some cases of hookworm disease not cured by thymol treatment, it does not explain another group of cases treated with thymol put up in mucilage of acacia, some of which it should be noted were of the extreme type. In some of these instances betanaphthol had been used and in others spirits of turpentine, with varied results.

To explain these cases by an acquired tolerance or immunity or some idiosyncrasy to the drug on the part of the individual seems to me to be fallacious. It should be remembered that the treatment of hookworm disease, in reality, is entirely confined to the worm and not to the patient and since the individual as such is not treated, it would be absurd to speak of an immunity or even an idiosyncrasy of the individual to thymol.

It seems to me that the explanation for the failure in the group of cases of unsuccessful thymol treatment is not to be found in a developed immunity or idiosyncrasy of the patient or worm to thymol, but rather in some peculiar physiologic or pathologic conditions present, or in faulty administration which prevents the *drug administered from reaching the parasite for efficient action.*

The form of administration has been touched on in the preceding: now let us see what physiologic or pathologic conditions can prevail which might prevent thymol from coming in contact with the parasite. Theoretically they are as follows:

1. A peculiar mucous or catarrhal condition of the small intestines. The parasite in its effort to hold on to the intestinal wall may be well buried in such mucus, or in the thickened mucosa, thus preventing the drug from coming in contact with it.
2. A viscous or colloidal state of intestinal fluid which might prevent intimate contact of crystals—for instance, a large amount of bile present.
3. The parasites produce small hemorrhagic erosions on the intestinal wall. When, as in the extreme cases, there are erosions enough, thymol may set up considerable irritation, which may produce vigorous peristalsis and thus propel the unattached intestinal contents with a sufficient degree of rapidity, to prevent the worm from being exposed long enough to the drug to be much affected by it. (It might here be stated that in the cases unsuccessfully treated, a partial relief from the disease is always obtained through the thymol; that is to say, a certain number of worms are killed or paralyzed and expelled).
4. The gastric or upper intestinal menstruum may be of a nature to dissolve the drug and permit of its absorption to a sufficient extent to relieve the worm of its toxicity.
5. Thymol may be administered in a form so as to reach relatively few worms, as discussed above.
6. In hookworm disease there is present generally, and in the severe cases always, an extreme of pot-belly, a great debility and a general enteroptosis. With a general enteroptosis and inactivity, dilatation of the stomach is a common association. It is easily seen how a drug may lie for a comparatively long period in such a stomach and fail to reach the parasite. Later, when carthartics are administered, the drug is propelled through the intestines so rapidly as to prevent sufficient exposure of the worms to the drug for efficient action.

That all these factors can play a part in protecting the parasites from the drug must be conceded. The importance of each factor would vary with each individual case, but of all these factors the last seems the more likely. I happened to see a case in a dog a few days ago which would seem to bear out this conclusion. The veterinarian in charge of the case gives the following history:

History.—A large English pointer of fine breed, three years old, considerably emaciated, extremely anemic and weak; mucous membrane white; constipation and no appetite. March 24, 3 p. m., a half ounce of epsom salts given; no action. March 25, 9 a. m., thymol, grains 25, given; 2 p. m., half ounce of epsom salts given; no action. March 26, 8 a. m., castor oil, drams 2; no action. March 26, 11 a. m., I saw the dog for the first time. Its condition was as follows: paralysis, shock, slow heart, slow respiration, fall of temperature, later followed by coma. Rectal irrigations were then given; strychnin, brandy and salt solution were injected subcutaneously. The dog sank slowly and died several hours later.

Autopsy.—General paleness and extreme anemia of all tissues and organs; heart-filaria fifteen in number; stomach full and greatly dilated; pyloric end closed; stomach contents thin, watery fluid; some solid remnants, hairs, etc., and remnants of cachets. The entire intestinal tract was extremely pale and literally covered with hookworms, even the rectum. The mucosa was much thickened with numerous hemorrhagic erosions scattered over it. In this thickened mucosa many of the worms were well buried and obtainable only by scraping with a knife.

Here is a case, if we can use this as an experimental one, of an intestinal system so depleted of blood and debilitated by disease that there was not sufficient power remaining to propel the stomach contents into the intestines. The dilation resulting offered an excellent reservoir for all material ingested. Water was not absorbed because of the epsom salts present. The castor oil administered dissolved what thymol was present in the stomach permitting its absorption, producing the poisoned condition in which the dog was found, and so debilitated was the animal from disease that it could not withstand the intoxication.

This danger in the treatment can be overcome to some extent if the patient be placed on the right side in bed (after administering thymol) as recommended by Stiles. This will permit mechanically more ready passage of stomach contents through the pylorus and incidentally a good deal of the burning sensation of the stomach will be avoided.

TREATMENT

The patient should have nothing to eat from noon of the day previous to the administration day of the thymol. On this day and the day following, fat of any kind, milk, cream, butter, bacon, etc., should be avoided. Whiskey, beer, wine and oils are absolutely interdicted, as all these can dissolve thymol. Early in the evening of the first day sufficient epsom salts should be given for efficient purgation. It is important that the bowels should be well moved. Early next day the dose of thymol decided on should be divided into two parts and given one hour apart. It is best administered in cachets triturated with equal parts of milk-sugar, and before using the cachets should be well softened in water until they are of the consistency of a raw oyster. It is best to put the patient to bed, on the right side. The thymol should be retained for from two to five hours, unless distress or symptoms of intoxication occur. (H. F. Harris, Atlanta, Ga.) Epsom salts should then be used for flushing the bowels and expelling the drug. The following dosage as outlined by the State Board of Health of Florida is considered safe to use:

Under 5 years of age	Up to 8 grains
5 to 10 years of age	8 to 15 grains
10 to 15 years of age	15 to 30 grains
15 to 20 years of age	30 to 45 grains
20 to 60 years of age	45 to 60 grains
Over 60 years of age	45 grains

In determining the size of the dose the *apparent age* and the real weight of the child should be considered. The condition of the heart, the degree of debility and anemia should also be considered. And where these latter conditions prevail to any extent small doses are indicated. The nauseating effects of epsom salts can be considerably lessened if dissolved in the smallest quantity of warm water possible and swallowed. This to be then followed by a large quantity of any mild fluid, even water. The mixing thus takes place in the stomach instead of in the glass. The patient may begin to eat after the bowels are well moved on this day. It is best that they should eat sparingly and avoid distress from engorgement. The same precautions should be observed on this day regarding fats, oils, alcohol, etc.

Once the worm is eradicated, fresh air, sunshine, plenty of water and proper food are the chief requirements for the treatment of the anemia of hookworm disease. Iron, arsenic, tonics and ferruginous vegetables are indicated. The patient should be treated at intervals of one, two or three weeks until the stool is free from eggs or parasites. The more debilitated patients should be treated at longer intervals.

Betanaphthol is not so toxic to the parasite as thymol, but has a more toxic action on the kidneys. The anthelmintic properties of turpentine are less than those of thymol; besides turpentine is less desirable because of its ready absorption and liability to produce an acute nephritis. Pressed thymol tablets should never be used.

REMOVAL OF NEOPLASMS OF THE URINARY BLADDER

A NEW METHOD, EMPLOYING HIGH-FREQUENCY (OUDIN) CURRENTS THROUGH A CATHETERIZING CYSTOSCOPE*

EDWIN BEER, M.D.

Surgeon to Montefiore Home; Assistant Visiting Surgeon to Bellevue Hospital; Assistant Adjunct Surgeon to Mount Sinai Hospital; Junior Surgeon to the New York Neurological Institute; Cystoscopist to the German Hospital

NEW YORK

This brief preliminary report is written with the object of calling the attention of the profession to a new and simple method of destroying new growths of the urinary bladder. Even though my experience is not extensive, limited as it is to two large papillary growths, still the observations made leave no doubt in my mind that the Oudin current, employed as I have employed it, will prove effective in the cure of benign papillomata, as well as useful in malign tumors, papillomatous or not, both as a hemostatic and as a cauterizing agent.[1] My experiences also suggest the usefulness of these currents in many other conditions both in the bladder and in other parts, e. g. tuberculous ulcers of the bladder, prostatic hypertrophy, growths in the urethra, etc.

In March, 1908, I hit on the idea of using the high-frequency current as I now use it. Expert electric manufacturers told me I could not obtain the effects I desired through a water medium; that an air gap was necessary. Moreover, that if I used the current as I intended, it would burn out my cystoscope. Others who had experience with these currents in skin conditions were equally pessimistic. Despite these opinions I ordered from the manufacturer a thoroughly insulated cable, No. French caliber, so that it could be introduced readily through the catheter tunnel of a Nitze catheterizing cystoscope. My experimental work was confined to the removal of skin warts through a water medium I soon convinced myself of the efficacy of this therapy, despite the absence of an air gap. I also tested my Nitze cystoscopes and found that they stood the test perfectly. They were not burned out and I could readily see what was going on at the end of the electrode though very rarely an insignificant variation in the intensity of the light occurred.

Through the courtesy of Dr. A. G. Gerster, I was able to try out this new method in an inoperable tumor of the bladder in a woman of 81. In a second case, that of woman of 66, I employed this method also. Both patients were troubled with hematuria. In the second case the bleeding was very active, while in the first case it was moderate when the treatment was begun. As my experiences in these cases were highly satisfactory, I hasten to lay them before the profession, that others may avail themselves thereof.

TECHNIC, ETC.

Instruments—1. I employed the Oudin current derived from a Wappler machine, placing the rheostat vertically so that one-half the resistance was thrown into the circuit. The spark gap in the muffler was approximately 1/10—1/8 inch.

2. Nitze, double-catheter cystoscope was used. In one catheter tunnel, I placed the electrode introducing it just as one introduces a catheter while to the other catheter tunnel I attached a tube for irrigation.

3. The electrode was a simple 6-ply cable of copper wire thoroughly insulated with rubber and cut off squarely at the vesical end. It measured No. 6 French and was made for me by the Wappler firm.

Application—The applications were made directly to the growth, the electrode being pushed a short distance in among the villi under the guidance of the eye and then the current was turned on for fifteen to thirty seconds at various points. The bladder was distended with distilled water. Experience may show that some other medium is preferable in view of the fact that ionization with magnesia appears particularly effective in removal of skin papillomata.

EFFECTS AND RESULTS

The immediate visible effects are very striking. No spark is seen even when the full current is thrown on without any resistance. While the current is on gas is generated quite freely and is seen bubbling out of the growth. If the point of application is superficial we can readily see a blanching of the tissues about the point of application; and at the spot where the electrode's point rested, the tissues are blackened—carbonized. As the electrode is withdrawn from the growth, very frequently it is found to be adherent to the villi, and as it is pulled on, the whole tumor moves with the electrode, which finally comes away with a piece of the tumor well baked to its vesical end.[2] This is only rarely followed by bleeding and a reapplication of the current at the same spot controls this bleeding. The great heat generated melts the insulating rubber at the end of the electrode so that one has to cut it off squarely from time to time, to prevent the wires from protruding freely and injuring the bladder wall.

In the second case the very first application of the current controlled the bleeding to such an extent that cystoscopy, which had been almost impossible, owing to the excessively rapid clouding of the medium from the arterial bleeding, became fairly easy. Eight applications at one sitting to various parts of the growth, aggregating in all four minutes, controlled the bleeding. In the first case, the hematuria was equally well controlled, but the result was less striking than in Case 2, in which the severe hemorrhage ceased at once and intensely bloody urine gave way to normal yellow urine.

---

* From the First Surgical Service of Mount Sinai Hospital.

[1] In early cases of malignant disease a complete destruction may be possible

[2] These fragments have been used for microscopic examination.

Such applications of fifteen to thirty seconds seem to cause a very well-marked necrosis, which is in part due to the heat engendered. Other factors probably contribute to the final result. How much ionization, electrolysis and other factors contribute, I cannot state as yet. By making applications at eight to twelve different points in the two large tumors treated, a total necrosis of all the villous outgrowths followed with absolute cessation of hematuria. Gradually during three to five weeks the dead tissue separated from the healthy and the tumors were expelled in small masses, as the mucous membrane gradually grew in around the base of the dead tissue.[3] No ulcers were visible at any time.

The treatment caused no more discomfort than an ordinary cystoscopy. The bladder mucous membrane was but little affected by the application though some congestion and trigonitis developed in the vicinity of the growths.

At some future date, I shall report these cases in full, which is hardly necessary for this preliminary note.

ANIMAL EXPERIMENTATION IN RELATION TO PRACTICAL MEDICAL KNOWLEDGE OF THE CIRCULATION*

JOSEPH ERLANGER, M.D.
MADISON, WIS.

(Continued from page 1684)

II. MODERN VIEWS OF AND METHODS OF STUDYING DISEASES OF THE CIRCULATION

In Part I of this paper the attempt has been made to present in the briefest possible form the fact that we owe our knowledge of the circulation primarily to animal experimentation. This paper has been written for the purpose of showing the practical bearings of the knowledge so gained on our understanding of certain phases of human pathology.

There could be no more emphatic way of bringing home to the practicing physician the practical results, so far as the cardiovascular system is concerned, that have accrued through the application to human pathology of the results of experiments on animals than to transcribe in full for his consideration the parts dealing with disease of the blood-vessel system, first, from some work that was standard before the Renaissance, i. e., before the importance of animal experimentation was fully realized, and, secondly, from a work that is standard to-day, calling attention to the differences between them and indicating how far such differences are due more or less directly to experiments on animals. Unfortunately, however, the limited scope of this paper precludes the full treatment of the subject in this way. I must, therefore, content myself for the present with brief extracts and discussions which, it is hoped, will furnish the reader material about which he may group his own ideas on the subject. It should be added that the extracts given below have not been selected at random, but only after careful consideration and as representing the views which, in my opinion, are in closest accord with those of the most enlightened thought of the time.

I select as the work from which to quote the views held prior to the revival of learning, "The Seven Books of Paulus Ægineta with a Commentary Embracing a Complete View of the Knowledge Possessed by the Greeks, Romans, and Arabians on all Subjects Connected with Medicine and Surgery,"[1] which dates from the seventh century. This work has been selected, first, because of its accessibility, and, secondly, because it purports to be a more or less complete compendium of the then known medicine.

The section on the heart is brief and may be quoted practically without abbreviation:

> When the heart itself is primarily affected, the case is far beyond all medical aid, occasioning sudden death; and also in the inflammations and erysipelas of it, strong distempers in very acute fevers, and hemorrhages when it is wounded, especially in the left ventricle. When it is affected sympathetically with the brain, the liver, the orifice of the stomach, and from sorrow, fear, and many other causes, it brings on the affection called syncope, being a sudden collapse of the vital powers, indicated by prostration of strength, delinquium animi, a small pulse, coldness of the extremities and copious perspiration. When this affection is of a violent nature, it also is irremediable; but if the strength stands out, it may sometimes be relieved. But strong palpitations of the heart often arise from a fulness or effervescence of its blood. When, therefore, the heart is overheated, it renders the respiration large and dense, but when it is too cold, the respiration is small and rare. The complete cure of syncope of the heart, when it occurs among the symptoms of fever, we have treated in the Second Book. This only may be added, that when collapse gains ground after friction and ointments have been applied to the extremities, and after purification of the floor, and other cooling means, we must sprinkle on the parts of the body which are sweating powdered myrtle, limolian earth, or amber, or pomegranate-rind with marena, or Samian earth with gum; and cataplasms of mustard or pellitory, adarce, are to be applied to the cold extremities, as far as to the groins and armpits. The food should be bread out of water, or out of cold diluted wine, swine's feet and joints and snout, and fowls; all things to be given in a cold state. . . .[2]

Under the topic of "palpitation of the heart" there is found the following interesting passage:

> "I knew a certain person," says Galen, "who suffered an attack of palpitation of the heart every year in the season of spring. Wherefore, having for three years experienced benefit from venesection, in the fourth he anticipated the attack by getting bled, and so escaped from it, and did so for many years afterwards, using at the same time a suitable diet. And yet even he died before attaining old age, as every other person in this complaint does, some being suddenly cut off in acute fevers by syncope; but some of them without syncope, being unexpectedly deprived of life, as if by apoplexy. The majority of those who are thus affected do not reach the fiftieth year of age, but pass the fortieth."

Finally the ideas held by Paul of Ægina in regard to dropsy are set forth in the following passage:

> Where the liver is greatly congealed, sometimes primarily, as when it has been inflamed, indurated, or otherwise affected, or when from sympathy with other parts the process of sanguinification ceases, and the affection is called dropsy. . . . But, for

---

* This paper is one of the series prepared for and reprinted by the Council on Defense of Medical Research of the American Medical Association for circulation among the public. Fourteen of these pamphlets are now ready, taking up the relations of animal experimentation to ethics, diagnosis, cancer, vaccination, the live stock industry, tuberculosis, typhoid, dysentery, plague, rabies, surgery, internal secretions, the circulation of the blood, protozoan tropical diseases, etc.

[3] If the flat base of the growth remains after the sloughing of the necrotic villi, these small areas must be treated in turn directly, to produce a cure. To avoid perforating the bladder, shorter application of fifteen seconds should be used here, such as I used in Case 1.

[1] Transl. by Adams, London, 1844.

[2] Paul of Ægina: Seven Books . . . , i, 501.

> the most part, it arises from hardness and scirrhus about the spleen and liver, and from chronic deflexions about the intestines; whereby it happens that the belly is swelled, while the rest of the body is melted owing to its not being nourished. . . . Sometimes throughout the whole body a colder and more pituitous blood is collected, either coming from the liver, or deriving its origin from a melting down of the flesh of the whole body, which is as it were converted into water. . . . In treating these complaints, we commence generally with evacuation; but in ascites and tympanites it is by administering hydragogue medicine; and in anasarca by blood-letting. . . . When those who have ascites are not benefited by any of the remedies already described, we must have recourse to paracentesis, which does not apply to any of the other varieties of dropsy.[3]

The quotations cited above show that the theory and practice of the time of Paul of Ægina, which are not to be scoffed at, are based on the physiology of Galen, who, by some, is considered the founder of physiologic experiments, carefully planned and executed.[4] It will do no harm to call attention again to the fact that the first careful experimenter, and the last to experiment prior to the Renaissance, was the authority of all practitioners through the long period of the dark and middle ages. And, it may be added, that so far as Galen's followers expounded views that were the result of experiments on animals, just so far were they indebted to animal experimentation for their clinical knowledge. It would carry me too far afield to attempt a detailed exposition of this dependence.

Nor is the modern practitioner any less dependent on the results of animal experimentation than were his predecessors.

> The problem for a physician to solve when confronted with a case of circulatory disease is, which of the many factors in the maintenance of the circulation are at fault? . . . The factors in the normal maintenance of the circulation are: an efficient myocardium with a sound directing innervation, efficient and unobstructing valves at the atrioventricular and arterial orifices, an aorta and branches of suitable caliber with elastic walls.[5]

The part that animal experimentation has played in determining this problem may be made clear by paraphrasing it to suit our purposes, thus: The animal experiments of Harvey, Malpighi and others have demonstrated that in animals the blood is propelled through the blood-vessels in a circle through the pump-like action of the heart, whose active tissue consists of muscle (experiments of Harvey,[6] Stenson[7] and Borelli[8]), not of parenchyma.[9] Clinical experience, viewed in the light of Harvey's experiments, has shown that in man, too, the blood circulates. In disease of the cardiovascular system the circulatory mechanism does not work properly. What is at fault? It may be Harvey's force-pump, not the (mainly) suction-pump of the earlier writers. The pump may fail to work efficiently through unfavorable action of the nerves which regulate its movements. That the nerves of the heart do not determine its action was demonstrated by the experiments of Haller[10] (1757); that the work of the automatic heart is regulated by its nerves was demonstrated by the experiments of the Weber brothers[11] (1845), who discovered the tonic action of the vagus mechanism, and by von Betzold[12] and Cyon,[12] who determined through animal experimentation the action of the accelerator nerve. The contracting myocardium can move the blood in a circle only through the medium of the valves of the heart. It is obvious that any one familiar with the structure of the valves could easily infer their mechanical action, provided the information was at hand as to whether the heart acted after the fashion of a force-pump or a suction-pump or both. Erasistratus seems to have been familiar with the action of the valves, but, swayed as he was by the belief that the heart alternately took in and expelled materials, his knowledge served neither his contemporaries nor his successors any useful purpose. After Harvey had, however, demonstrated the true action of the heart and after this action had been more convincingly demonstrated by the animal experiments of Marey[13] and others, further experiments were needed only for the purpose of working out the finer details of the valvular mechanisms. The need of "efficient and unobstructing valves" became obvious. The mechanical advantages of elastic tubing in the maintenance of the circulation were pointed out by the animal experimenter, Borelli,[14] and the whole question was studied in greater detail by S. H. Weber[15] (1850).

All of the factors in the maintenance of the circulation, then, which a modern clinician considers of prime importance have been brought to light directly or indirectly through animal experiments.

Pre-Harveian treatises on diseases of the blood-vessel system, therefore, differ from modern works on the same subject in at least two fundamental respects: 1. The foundation of the latter consists of a clear conception of the function of the parts concerned, this conception being based for the most part on demonstrated facts. 2. It is recognized in modern treatises that disease is due to disturbed function.

It is interesting to trace in somewhat greater detail the effect that the discovery of the circulation of the blood and the consequent renewed activity in experimental physiology had on the discovery of diseases of the heart. It has been shown that before the time of Harvey diseases of the blood-vessel system received very scant mention in the standard texts. Excepting treatises on the pulse and on bleeding, the writings on the subject were very scant indeed, while but very few distinct diseases were recognized. Of diseases of the heart and symptoms, mention is made in pre-Harveian literature only of hydrops pericardii, syncope, palpitation, erysipelas, abscess, tumors and wounds, the mythical *cor hirsutum,* and, late in the sixteenth century, dilatation, and these conditions were very imperfectly understood.

On the other hand, within the hundred years whose beginning is marked by the publication of Harvey's tract (1628) distinct progress toward the modern conception of cardiovascular disease can be discerned. Harvey himself describes a case of rupture of the left ventricle, and a case of *cor bovinum* with dilatation of the aorta, together with the symptoms during life. Lower, one of a trio of brilliant animal experimenters of Harvey's time, discusses hydropericardium as a result of venous stasis, and also a case of adhesive pericarditis.[16] Cooper described aortic insufficiency and appreciated its significance.[17] The same lesion as well as stenosis of the mitral orifice, with an ingenious explanation of the pulse quality in that disease, as well as many other interesting references to cardiac disease encountered in the course of his practice, are mentioned by Vieussens in a work devoted primarily to the normal structure and functions of the heart.[18] Finally, in a work on the movement of the heart and on aneurisms, Lancisi makes many important contributions to cardiac pathology and pathologic physiology.[19] Besides making many other valuable additions to our knowledge, he ascribes sudden death to structural defects, mechanical obstructions and nervous diseases of the heart. He is the first to call attention clearly to the significance of engorgement of the veins of the neck in dilatation of the right cavities of the heart, a diagnostic sign of great importance which could not have been comprehended had Lancisi had at his disposal only the ancient view that the veins and the blood originate in the liver. In this connection he speaks of tricuspid insufficiency. He also understood almost perfectly the symptoms of dilatation of the heart and their cause.

The most important of the early works on diseases of the heart appeared, however, something over a century later than Harvey's great contribution. This is Senac's "Treatise on the Structure of the Heart, on its Action and its Diseases" (Paris, 1749). Perhaps the most striking feature of this work is its modernness. There is no difficulty in comprehending the conditions described by the author; so modern are the thoughts that the reader can hardly believe that he has before him a work written over one and one-half centuries ago. I am of the opinion that Senac's pre-eminence in the field of cardiac pathology must be attributed largely to his grasp of the anatomy and physiology of the heart. However this may be, it is not without significance that of the two large volumes Senac has written on this subject about one and one-half are devoted to an exposition of the anatomy and physiology of the circulation.

Of his many important contributions, space will permit of reference to but one. To Senac must be attributed the recognition of the venous pulse as a diagnostic sign. At the same time he recognizes the most important factor in its production. Speaking of dilatation of the right auricle, he says (p. 411): "It is evident that dilatation of the vena cava should be no less frequent; the blood is pushed with force when contraction diminishes the cavity, and this is the cause of a singular phenomenon; the jugular veins beat with regularity. . . ." Whether Senac was here dealing with the pulse produced by a hypertrophied right auricle or by regurgitation through the tricuspid orifice cannot be determined. From our standpoint, however, it matters little, since in either case the phenomenon, without a knowledge of the "motion of the heart," would have been without significance as a diagnostic sign.

At about the same time Morgagni,[20] the father of pathologic anatomy, called particular attention to the mechanism of the circulatory disturbances caused by valvular lesions and explained the symptom of cyanosis as a congestion of blood.

DEVELOPMENT OF CLINICAL METHODS

Through animal experimentation coupled with inferences from anatomy, the circulation of the blood in animals was demonstrated. Observations on human beings sufficed to show that the results of animal experiments were applicable to man without change. And finally clinical conditions were gradually recognized in the light of normal function and a more logical classification of disease became possible. Except, however, the relation between right-sided lesions and venous engorgement and pulsation, exact methods of recognizing pathologic conditions in living man were, aside from the evident symptoms exhibited by the patient, almost entirely lacking. It is to the relation which the development of these methods bears to animal experimentation that attention will next be directed.

At the outset it should be made clear that the problem of developing methods must, from the nature of the case, be largely clinical, since what are desired are methods for the detection of conditions which are commonly seen in man, and rarely in animals, and which may be studied in animals usually only after the diseased condition as disclosed in man has been reproduced in animals.

The methods now employed by the physician in his effort to detect deranged function of the organs of the circulation are usually classified under the heads of inspection, palpation, percussion and auscultation. Three of these principles, namely, inspection, palpation and auscultation, are as old as the seeing eye, the feeling hand and the hearing ear. Their origin, therefore, bears no relation to animal experiments. The same statement is not, however, true of their subsequent development and elaboration. The eye must be trained to see and the hand to feel. Few of us are gifted with the power of seeing or feeling what others before us have failed to see or feel. Yet the eye or hand when provided with a working hypothesis or a demonstrated fact can often discover or discern phenomena which otherwise might have escaped them entirely. For instance, Galen, than whom the world has had no keener observer, must frequently have watched the beating heart exposed in animals—he actually records having seen the beating heart of man, exposed by disease—yet he failed to recognize what Harvey discovered in the same way, but probably with his working hypothesis more or less fully developed, namely, that the active phase of the heart's motion, and the phase corresponding with the pulse in the arteries, is its systole and not its diastole. To the student of to-day, guided, as he is, by demonstrated fact, it is almost inconceivable that any one could for a moment have held any but our present view in regard to the motion of the heart.

Inspection

And so it is that to-day pallor, cyanosis, dyspnea, pulsation in the veins and arteries, as well as many other visible signs of disease are quickly recognized even by the beginner and their significance almost as quickly grasped.

Whereas pallor now, and as was probably the case even at the time of Hippocrates, denotes bloodlessness, we of to-day have learned to distinguish between pallor of several different origins; for example, the pallor of anemia, of deficient heart action (of nervous origin),[21] of deficient vasomotor tone in the splanchnic area,[22] the two latter conceptions arising out of animal experiments, and the pallor of localized vasomotor overaction,[23] likewise a conception which the clinician owes to physiologic experiments. The ability to distinguish these and other types of pallor is not merely an accomplishment devoid of all practicality; rather it is through this ability that the practitioner is placed in a position to discover causes and to remove them by means of rational treatment directed specifically to them and, if it is so desired, to nothing else.

[22] Ludwig and Cyon, 1866. Quoted by Luciani: Lehrbuch der Physiologie, i, 281.

To be somewhat more specific, I shall quote for purposes of illustration a passage from Paul of Ægina. Under the title of "Deliquium Animi or Swooning" (one of the topics treated under "Fevers") this author says:[24]

> Several strong ligatures are likewise to be applied; when the evacuations are downward, to the arms, and, when upward, to the legs. The patients are also to be placed in an easy erect posture, and a cupping instrument applied, so as to produce revulsion to the opposite part of the body. . . .

It is quite unnecessary to call the attention of the reader to the points at which the above (which probably is largely Galen's) treatment is at variance with ours, which is dependent on modern conceptions, both mechanical (Spallanzani[25] (1729), Haller,[26] and others) and vosomotor (Bernard[23] and others) of the circulation.

Cyanosis, too, has always been recognized; but how, in the absence of facts brought to light by animal experimentation, could the distinction be made between the cyanosis of acquired heart disease, where it always is an indication of back-pressure into the veins from a congested right heart,[26] the cyanosis of insufficiently aerated blood (Lower, Mayow and Guericke, Lavoisier and others[27]) and the cyanosis of local asphyxia, probably of vasomotor origin (Bernard,[23] Thompson[28] and others).

Dyspnea as a symptom of cardiovascular disease is occasionally hinted at by the early writers. Thus, Paul of Ægina says: "When the heart is overheated it renders the respiration large and dense, but when it is too cold the respiration is small and rare."[29] This relation between the heart and the respiration was probably suggested by the Galenic doctrine that the main functions of respiration were to remove from the body the fuliginous vapors and to cool the blood which is warmed by the innate heat of the heart. That there is an element of truth in this doctrine cannot be denied (and we should not lose sight of the fact that this, in large part, is the fruit of animal experiments), yet it is evident that such a view would have been entirely inadequate to bring to light the true clinical significance of cardiac dyspnea. Deficient internal respiration due to slowing of the blood-stream (a sequel to the demonstration of the circulation) and engorgement of the lungs, on which depends also the hemoptysis of heart disease (Albertini[30]), now account quite satisfactorily for this condition and suggest lines of treatment.

Palpation

The way in which the animal experimenter has helped our hands to feel for clinical states also may be illustrated by a few examples.

From time immemorial the pulse has been held to have great diagnostic value. Indeed, until quite recently and even now in some parts of the world, China, for instance, a great deal more significance was or is attributed to the pulse than is justified by experiment. The result was that classification of the pulse was carried to a degree of refinement that is bewildering. Thus, Sanctorius, in 1625, recognizes seventy-three significant kinds of pulse.[31] His time probably marks the pinnacle of pulse analysis. With the advent of careful experimental methods, as laid down by Harvey, and largely through the efforts of experimentalists, the Weber brothers[32] in particular, and down even to the present day[33] the number of significant varieties of pulse has constantly diminished. And, what is of far greater interest, the significance of the few varieties now recognized has become far more definite. The first step toward this simplification was made by Harvey when he recognized the right relation between the contraction of the heart and the pulse in the arteries. Paul of Ægina thus explains the Galenic view of the pulse:

> The pulse, is a movement of the heart and arteries, taking place by a diastole and systole. Its object is twofold; for by the diastole, which is, as it were, an unfolding and expansion of the artery, the cold air enters, ventilating and resuscitating the animal vigor . . .; and by the systole, which is, as it were, a falling down and contraction of the circumference of the artery towards the center, the evacuation of the fuliginous superfluities is effected. . . . They (the arteries) arise from the heart, and are distributed to all parts of the body, and, therefore, all the arteries pulsate in a similar manner and like the heart, so that from one of them you may judge concerning all the rest.[34]

The fact that "all the arteries pulsate in a similar manner and like the heart" is the very foundation of the diagnostic significance of the pulse. Naturally, however, the errors in the Galenic conception dragged into medicine along with them many misconceptions with regard to the mechanism of the pulse, and consequently led the physician to feel events which actually do not transpire. For instance, we find that, in accord with the idea that the pulse consists of an active systole and an even more active diastole of the artery itself, the Galenists divided the time of rest between pulses into the diastolic rest and the systolic rest. With the adoption of the views on the pulse as determined by Harvey, by the Weber brothers, animal experimenters, and with the invention of the first practical sphygmograph by animal experimenters (Vierordt[35] and Marey) the clinicians came into the right conception as to the form and time relations of the pulse: the distinction made by the Galenists, which we now know to be without foundation in fact, is no longer taught. The chief value of the sphygmograph, it should here be added, does not consist in the means it affords us of making for purposes of study a graphic record of the pulse, although this result is not to be undervalued; rather it is that the knowledge of the true form of the pulse-wave as determined with the sphygmograph makes it possible for the student to discern more easily and to value by simple palpation what otherwise he might never, or only after diligent application, learn to discover.

It may reasonably be doubted whether the Galenists had any clear ideas in regard to pressure and pressure variations in the arteries and veins. It is true that in

their classification of pulses they speak of the "consistence of the body of the artery"[36] and distinguish three varieties thereof, namely, hard, soft and moderate; yet it cannot be made out from the context whether "consistence" is a property of the arterial wall proper or one imparted to it through the pressure of the blood in the lumen.

However this may be, we owe to the Rev. Stephen Hales[37] the demonstration, by means of his classical experiments on animals, of the pressure in the arteries and veins and some of their variations. These experiments, multiplied and analyzed by subsequent investigations (Ludwig,[38] Marey[39] and others), gave to the practitioner a new clinical idea, that of attempting to determine by palpation the degree of arterial tension and to correlate tension with the clinical picture as a whole.

It was Traube who introduced the term "tension of the arterial wall" into the clinic. He had so often felt of the exposed artery of animals and had so often compared this with the pressure as measured by a manometer connected with the artery that he was in a position to estimate through palpation alone the pressures in man.[40] But Traube's method of training the touch is not a practical one for general use. Furthermore, palpation of pulse tension, like palpation of pulse form, had to be controlled and taught with the aid of some instrument of greater precision than the finger. The sphygmomanometer, the first practical form of which was devised by an animal experimenter and clinician (von Basch[41]), and which has been tested by animal experiments, was the result of this need. With this instrument Cushing,[42] guided by experiments performed on animals, discovered not only a sign of intracranial hemorrhage, but also a signal for operative interference in that condition. Most of the work in this field, however, is so recent that it is hardly necessary to refer specifically to other practical results that have come of it in the diagnosis, prognosis and treatment[43] of cardiovascular disease. I cannot refrain, however, from making a brief reference to a recent report by Williamson showing the prognostic value of blood-pressure estimations. Of seventeen patients with a blood-pressure over 200 mm. Hg. (the normal is about 120) Williamson was able to keep track of thirteen. Of these, eight had died within from two to three years.[44]

Neither inspection nor digital palpation sufficed for the correct analysis of the venous pulse. This was not possible until we had at hand the results of animal experiments (Riegel,[45] Frédéricq,[46] Porter[47] and others) and until such results had been applied practically in the analysis of the human venous pulse (Riegel,[45] Mackenzie,[48] and others) through the use of graphic methods primarily developed by animal experimenters (Ludwig, Marey and others). This whole subject is so new that it is quite unnecessary to remind the clinician of the practical results in the diagnosis of cardiac disease that have accrued therefrom.

Percussion

The direct object of percussion is anatomic rather than physiologic; it seeks to determine the limits of organs and the nature of their contents. Its indirect object, however, is to discover disturbed function. It therefore follows that the intelligent interpretation of the secrets brought to light by percussion can be made only by one who is familiar with the physiology, normal and pathologic, of the organs of the body. I quote in this connection the views on this subject held by Corvisart, the practitioner first to employ intelligently the method of percussion for the purpose of discerning cardiac disease. In his epoch-making work, in which are set forth the results of his clinical observations, Corvisart first discusses the relation of the development of anatomy and of pathologic anatomy to diseases of the heart and then proceeds to say:

> But it were very erroneous to think morbid anatomy sufficient to accomplish this end; it is quite the reverse; the physician who does not unite physiology [when I say physiology, I mean, once for all, the physiology of experience and observation (ever-cautious of the too easy indications from analogy) but not the systematic physiology which is often supposing, and constantly explaining] with anatomy will ever remain a more or less dextrous, industrious, and patient inquirer, but he will never become a firm and decisive practitioner, particularly in the treatment of the organic lesions.[49]

The facts brought to light by percussion, then, are, in the opinion of the founder of cardiac nosology, of the greatest significance only when viewed from the standpoint of experimental physiology.

Auscultation

Who, if not the practicing physician, would be expected to discover the sounds emitted by the beating heart? The nature of his work requires that the clinician keep alert all of his senses in his effort to bring to light the diseases he may encounter in his practice. The time and energy devoted to human beings for this purpose far exceed those devoted to animals. Yet Harvey, animal experimenter, as well as clinician, seems to have been the first to call attention to the fact that, simultaneously with pulsation, a sound can be heard in the chest.[50] To the practitioner Laennec, however, belongs the credit of developing clinical auscultation.[51] Whether or not Laennec himself performed experiments on animals I have been unable to determine. As a pupil of Corvisart (see above) he must, however, have taken at least an active interest in experimental physiology. That he did avail himself of the results of animal experimentation in the interpretation of auscultatory phenomena is seen in the following quotation, which at the same time will serve to indicate that had Laennec had just a little more first-hand knowledge of the action of the heart he might have succeeded in making a better interpretation of the facts revealed by his clinical observations.

> At the moment of the arterial pulse the ear is slightly elevated by an isochronous motion of the heart, which is accompanied by a somewhat dull, though distinct sound. This is the contraction of the ventricles. Immediately after, and without any interval, a noise resembling that of a valve, or a whip, or the lapping of a dog, announces the contraction of the auricles. . . . Immediately after the systole of the auricles there is a very short, yet well marked interval of repose. . . . This state of quietude after the contraction of the auricles

does not appear to have been known to Haller as a natural condition.[52]

Laennec therefore accepts without question the fact shown by Harvey and later first utilized by Albertini[53] as a diagnostic sign, that the apex-beat occurs with systole; while at the same time he calls attention to what he believes to be an oversight on the part of Haller—by many considered the father of modern experimental physiology—in regard to the time relation of auricular and ventricular systole.

But if Laennec had only taken the pains to examine an exposed beating heart in the light of his clinical observations, he never would have made the mistake of attributing the second sound to the contraction of the auricle, nor would he so quickly have jumped to an erroneous conclusion in the face of the results of direct experimental observation. Not very many years had elapsed, however, when Turner,[54] interpreting correctly the results of physiologic experiments as recorded in Haller's "Elementa," objected to Laennec's views on the cause of the second sound on the ground that the contraction of the auricles precedes that of the ventricles, and does not follow it as Laennec had assumed.

The limits of this paper make it impossible to trace for the reader the development of our knowledge of the cause of the heart sounds.[55] The statement must suffice that through combined clinical (Laennec, Skoda, etc.) and experimental observation, the most noteworthy of which were made by a committee of the British association under the leadership of Williams,[56] and the later experiments of Hürthle[57] and others, we are now quite certain of the true relations which the sounds bear to the events of the cardiac cycle, notwithstanding the existence at the present time of some uncertainty as to the causes of some of the normal sounds. With regard to abnormal heart-sounds, deductions from normal physiology as well as experiments in pathologic physiology have served to indicate to the clinician their meaning and even their diagnostic value. For example, a ringing aortic second sound indicates to the clinician an abnormally high aortic tension. Harvey's experiments in themselves might have suggested this, but the conclusive proof of it was offered by the experiments of Williams and others, who showed that the second sound arises in the arterial valves and that its intensity diminishes when the arterial tension is lowered. If the reader is desirous of further instances of this nature he may consult any of the modern handbooks on diseases of the heart; for example, the article by Gibson on cardiac insufficiency in Osler's "Modern Medicine," which he will find to be practically an article on applied physiology—physiology made up almost exclusively of experiments on animals.

SOME ALLEGED EFFECTS OF SODIUM BENZOATE AND BENZOIC ACID

C. A. HERTER, M.D.
U. S. Referee, Professor of Pharmacology, Columbia University; Consulting Physician, City Hospital
NEW YORK

In a recent number of this journal[1] Dr. D. R. Lucas has published certain statements in regard to the action of benzoate of soda which are so much at variance with facts as to call for criticism and correction. The circumstance that these statements have emerged from the laboratory of a leading university is liable to secure for them a hearing which would scarcely be accorded otherwise.

I have no intention of entering here on a detailed examination of the claims set forth in the paper to which I refer; but there are a few points on which I deem it my duty to make at least some comment, despite the fact that this task is highly distasteful to me.

I

At the beginning of the paper there is presented a table showing the influence of various drugs on the action of ferments. This table is based on data given many years ago by T. Lauder Brunton and is designed to show that benzoic acid exerts a relatively strong inhibiting action on emulsin, pepsin, etc. The generalization is then made that from these data it is evident that the inhibiting action of the given amounts of benzoic acid in combined form (e. g. sodium benzoate) is very much weaker than when the benzoic acid is free. This statement, which on superficial observation appears very damaging to benzoic acid, is exactly paralleled by the platitude that sodium chlorid has a much weaker action than free hydrochloric acid. In other words, it is a statement which is true of acids in general, as has long been well known. As a matter of fact the figures given by Brunton and quoted so confidently in the above-mentioned paper, have been shown by Dr. Dakin to be entirely erroneous and misleading, as I shall show in detail in a forthcoming publication.

Here it must suffice to state that the claim that peptic digestion is easily arrested by benzoic acid in the proportion of 1 to 200 is entirely erroneous. Peptic digestion may proceed actively under suitable conditions in a solution completely saturated with benzoic acid, although naturally here the velocity of the action is diminished. One-tenth of 1 per cent. of benzoic acid retards peptic digestion about 12 per cent. When the circulation of free hydrochloric acid is low the effect is still less. One-tenth of 1 per cent. of benzoate of soda has no marked effect on tryptic digestion of casein. Seven-tenths of 1 per cent. of benzoate of soda has about 10 per cent. retardation.

These figures are true for human trypsin as well as for that of animals. It is thus evident that no important effects on peptic or tryptic digestion are exerted *in vitro* by the above mentioned concentrations.

II

Dr. Lucas' paper contains the statement that "sodium benzoate in proportions equal to about 1 per cent. was found to be a poor preservative of neutral or weakly acid media." It is true that sodium benzoate is not a powerful preservative, but the statement just quoted is highly misleading for the reason that most bacteria in media neutral to litmus (e. g. sugar bouillon) are very much retarded in their growth or wholly inhibited by percentages of sodium benzoate ranging from 0.2 per cent. to 0.5 per cent. For example, Professor Theobald Smith of Harvard University found that the growth of typhoid bacilli was greatly retarded by 0.3 per cent. of sodium benzoate and completely inhibited by 0.5 per cent.

---

[1] Lucas, Daniel R.: Some Effects of Sodium Benzoate, The Journal A. M. A., March 5, 1910, liv, 759

III

The statement is made that "benzoic acid, liberated from sodium benzoate by strongly acid fruits or vegetables and taken in them, even in small amounts, into an empty stomach, is sufficiently irritating to cause gastro-intestinal disturbances as well as systemic symptoms." It is, of course, obvious that acids, when liberated from their salts by other acids, are more apt to act as irritants than when these acids are neutralized by bases. And naturally benzoic acid is no exception to the general rule.

The assertion that injurious effects are obtained on the digestive tract and on other parts of the body is based on conditions very foreign to anything that happens in the course of any sane habit of diet. Large quantities of acid fruit-juices were employed in these experiments. In the second place, these acid materials were taken on an empty stomach. In the third place, the concentrations and the amounts of benzoic acid taken were far in excess of any quantities that would be consumed by persons in a normal state of mind and with a normal appetite. There is one possible exception to the latter statement and that is in the case of cider, which a person sometimes so gormandizes as to consume several liters of cider in the course of a few hours. Even here it is hardly conceivable that more than 2 or 3 gm. of free benzoic acid would be ingested.

IV

The character of the expedients employed to show the detrimental action of sodium benzoate is well shown in the pointless experiments on dogs, which were fed enormous doses of sodium benzoate from which the acid was liberated by means of hydrochloric acid and citric acid. Among others, the following is reported: A fasting dog weighing 3.5 kilos received sodium benzoate and hydrochloric acid in a preliminary experiment. The day after recovery from muscular weakness, nausea, etc., it received four gm. of sodium benzoate in an amount of hydrochloric acid theoretically sufficient to decompose it completely to free benzoic acid, together with 100 c.c. of a 2 per cent. citric acid solution. The animal became very weak, developed convulsions and died soon after the dose, showing congestion, ulceration and hemorrhage, etc. in the digestive tract, liver and lungs.

Anyone who will reflect on what this experiment represents in the way of benzoic acid in a human being will see that it is equivalent to giving 80 gm. of benzoate of soda to a man weighing 70 kilos. The effect in such an experiment is to liberate benzoic acid in its most concentrated form, to say nothing of free solid benzoic acid. How any other outcome than gross damage to the digestive tract was to be expected it is difficult to see, the results obtained being merely in accord with what every pharmacologist knows to be the action of strong acids. The fact that dogs receiving hydrochloric acid and citric acid in considerable quantities without benzoic acid did not become sick and die presents no unexpected features. It is doubtful if any competent, fairminded investigator, or anybody gifted with a sense of humor would put forward such an infelicitous experiment as the one quoted above as an argument in regard to the action of benzoic acid as a food preservative.

V

Among the claims made in regard to the injurious action of benzoic acid is the one that the presence of benzoic acid in acid fruits and fruit-juices gives rise to albuminuria, sometimes associated with nephritis. Experiments made in my laboratory with the administration of several grams of free benzoic acid daily in apple-butter or cider, failed to show the presence of albuminuria. In one of our subjects a faint trace of albumin was found from time to time during the experiments and also at other times. A careful expert examination with the cystoscope showed a slightly tender spot in the posterior urethra. No casts or evidence of renal irritation were found. Similar experiments with large quantities of benzoic acid in acid media have been made by various colleagues, including Professor Long,[2] without any of the results described in Dr. Lucas' paper.

The circumstance that the blood possesses an abundance of alkali with which to neutralize free benzoic acid, even in doses far above those obtainable in preservatives, explains why this acid, ingested in moderate amounts, can give rise to no injury of the kidneys, since the salts of benzoic acid, like the salts of most ordinary acids, are without injurious effects on the kidneys. It is necessary for those who are responsible for the claim that benzoic acid is the cause of albuminuria to give the exact methods by which the presence of albumin was ascertained—a precaution which is omitted in the published results. In this connection it should be recalled that benzoic acid was formerly used freely in bladder disease in large doses without any evidence that it was injurious to the kidneys.

VI

The tables in the paper under discussion give the impression that when benzoate of soda is ingested it is followed by the appearance of reducing substances in the urine attributable to the benzoic acid. Unfortunately the author has committed the flagrant error of making no adequate controls based on the action of cider alone. I wish to state that unbenzoated cider, 2 liters in the course of the day, in many persons gives rise to a marked increase in the reducing substance of the urine. For this reason it is wholly unfair on the strength of the data given to implicate benzoic acid in the causation of the reducing action noted. There is not the slightest evidence that this is the case. On the contrary, a series of experiments by Dr. Wakeman, made with scientific accuracy, showed that the action of benzoated cider was exactly paralleled by the action of unbenzoated cider. An accurate comparison of the varying reducing power of the urine with Fehling's solution can be excessive must suggest an injurious action of which definite volumes of Fehling's solution and of urine of definite specific gravity are employed and boiled for the same length of time, the results being recorded after a definite lapse of time. These essential precautions have been wholly neglected in the paper under consideration.

---

[2] Professor Long reports the results of experiments on three men who drank strongly acid lemonade containing benzoate, through a period of five days. The average acidity of the lemonade was 0.14 normal (equivalent to 8.4 grams of acetic acid per liter), and the amounts consumed were as follows, in the mean: Subject 1, daily, 700 c.c. of lemonade with 2.6 gm. of benzoate; subject 2, 700 c.c. of lemonade with 2.9 gm. of benzoate; subject 3, 600 c.c. of lemonade with 2.4 gm. of benzoate. The highest amounts of benzoate taken daily were 3.75, 5.00 and 5.00 grams respectively. Careful tests of the urine through the five days of the experiment, and for several days subsequently, failed to show the presence of even traces of albumin, or of reducing substances acting on Fehling's solution. No abnormal behavior of any kind was observed.

It is well known that large doses of benzoate of soda (10 to 20 gm. daily) cause the appearance of increased reduction in the urine due to the glycuronic acid. Somewhat smaller doses may sometimes suffice to do this. The relatively small quantities taken in benzoated cider do not suffice to produce this effect. The reducing substance present after taking very large doses of sodium benzoate has nothing whatever to do with the appearance of sugar in the urine and this point should be clearly understood.

VII

One other instance may be mentioned of the incorrect statements in which this paper abounds. The statement is made that after taking benzoated cider "excessive amounts of hippuric acid were eliminated." It is not clear what is meant by excessive amounts of hippuric acid, but the implication that the amounts observed were excessive must suggest an injurious action of which there is, of course, no evidence whatever. That this implication is clearly the intent, in the paper under consideration, is shown by the coupling of the above statement with the information that the urine was reduced in amount.

Not the remotest evidence exists that the excretion of hippuric acid, even in very large amounts, ever causes any damage to the kidneys. On the contrary, the evidence is all in the other direction. The paper quoted leaves us entirely in the dark as to what constitutes an excessive amount of hippuric acid and it surely would be no easy matter to give any rational meaning to such an expression.

If it were worth while to cite further examples of the untrue statements with which this paper abounds it would be an easy undertaking. But I think that enough has been said to show the unreliable and biased nature of Dr. Lucas' publication; and it may safely be left to the fair-minded reader to put a valuation on the conclusions of the paper in question.

PANCREATITIS FROM THE STANDPOINT OF THE CLINICAL SURGEON

A. J. OCHSNER, B.S., F.R.M.S., M.D.
Surgeon-in-Chief, Augustana Hospital and St. Mary's Hospital; Professor of Clinical Surgery in the Medical Department of the University of Illinois
CHICAGO

Since the surgeon has come to consider pancreatitis habitually with the same uniform system that he considers all other important intra-abdominal pathologic conditions, our appreciation of its importance as well as our knowledge of this condition have acquired reasonable dimensions.

ETIOLOGY

In 1895 my attention was directed to the practical side of the subject during a visit to Mayo Robson's clinic in Leeds, but it was only after his enthusiastic presentation[1] before the International Congress in Paris in 1900 that I really awoke to an appreciation of the value of his observations. Undoubtedly, the infection usually travels up the common duct into the gall-bladder where there is a possibility for the accumulation of a large quantity of infected bile mixed with mucus, which on its way down the common duct is easily diverted into the pancreatic duct if there is obstruction owing to the presence of gall-stones or of edema below the point at which the duct of Wirsung empties into the common duct.

In my cases the irritation of the common duct has been due quite as often to the passage of infected sandy bile as to the presence of gall-stones.

There is much difference in the statistics of various authors regarding the relative frequency with which pancreatitis accompanies gall-stones. This is probably due to the fact that the diagnosis of pancreatitis is based on the impression the surgeon obtains from palpating the gland during operation, and one surgeon may consider the gland practically normal in an individual instance in which the same condition would impress another surgeon as representing a certain degree of enlargement.

Unless a surgeon has examined many cases in which the abdomen was opened for conditions which could have no relation with the condition of the pancreas in order to become familiar with the feeling of a normal pancreas it is not likely that his judgment in this matter can be entirely satisfactory.

It is therefore well to palpate the pancreas in cases of operation for the removal of uterine fibroids or ovarian cysts and other similar conditions. This can be done readily while the surgeon's hand is in the upper portion of the abdomen for the purpose of examining the gall-bladder.

All surgeons with large experience in this especial direction seem to agree that pancreatitis patients almost invariably suffer from disease of the gall-bladder or ducts and that gall-stones in the common duct are more commonly accompanied with pancreatitis than stones in the gall-bladder (Robson,[2] Mayo,[3] Moynihan,[4] Egdahl,[5] Opie.[6])

It has been suggested by Williams and Bush,[7] and apparently confirmed by careful experimentation, that anatomic peculiarities interfering with the free drainage of pancreatic juice through the ducts of Santorini or Wirsung provide favorable conditions for the infection of the pancreas. It is plain that when the natural conditions for free drainage of pancreatic juice are unfavorable, complete obstruction, due to the presence of gall-stones or edema, is much more likely to occur.

The colon bacillus is the most common cause of the infection, and this is frequently associated with the streptococcus and the staphylcoccus, according to the investigations of Egdahl[5] and others.

Pancreatitis, in common with all inflammatory diseases of the gall-bladder and ducts, frequently follows the inflammatory diseases of the gastro-intestinal tract.

After the pancreas has once been infected a species of vicious circle is developed from the fact that the swollen pancreas obstructs the portion of the common duct which passes through the head of this organ, and this favors the development of septic micro-organisms above this point as well as their further backing up into the pancreas. It is for this reason that the free drainage due to cholecystostomy has given such uniformly favorable results.

PATHOLOGY

All these facts seem to bear out the theory commonly accepted at the present time that, barring the rare occurrence of metastatic infection, pancreatitis is due to infection from the alimentary canal, usually through the biliary passages, or, according to Maugaret, more especially through the lymphatic system of these passages. The acute violent cases of hemorrhagic pancreatitis are apparently due to retrograde injection of the pancreas with infected bile and pancreatic juice which, according to Flexner, must be in a relatively concentrated form.

In these cases which take a violent acute course there is commonly a rapid destruction of the gland parenchyma.

In the chronic forms, on the other hand, the inflammation results in interlobular fibrous tissue hyperplasia. The secreting cells of the acini are more readily destroyed than the islands of Langerhans. This fact would account for the relative infrequency of glycosuria in mild or early cases of pancreatitis.

DIAGNOSIS

Until recently the diagnosis of pancreatitis was made incidentally only during the progress of operations on the gall-bladder or biliary tracts and the stomach. Since the attention of the surgeons was generally directed to this condition by Mayo Robson,[1] Riedel,[9] Mayo and others, the diagnosis has frequently been made before and confirmed during the operation. From this it has become possible to associate the condition of pancreatitis with a number of more or less typical diagnostic signs observed before operation.

In 1904 Cammidge,[10] in connection with the clinical work of Mayo Robson, brought out a most ingenious chemical test which promised to be of great value in the diagnosis of this condition.

The method has been described most clearly by Schroeder,[11] as follows:

> Forty c.c. of the urine, filtered, acid reaction, free from albumin and sugar, are boiled with 2 c.c. of strong hydrochloric acid for ten minutes. After partly cooling, 8.0 gm. of lead carbonate are gradually added. When the reaction is complete, the mixture is chilled, filtered and the excess of lead in solution removed by addition of 2 gm. of sodium sulphate bringing the mixture to a boil, chilling and filtering to 20 c.c. To this filtrate is now added a mixture of phenylhydrazin hydrochlorate 0.80 gm., sodium acetate 2.0 gm. and of 50 per cent. glacial acetic acid 1 c.c. and the whole is boiled on a sand-bath for ten minutes. The solution is then filtered while hot and set aside to crystallize. The precipitation of crystals, sometimes only in microscopic quantities, of the characteristic formation of ozazones, makes a positive reaction.

In 1905 I had a large number of tests made at the Augustana Hospital laboratory on patients who were later operated on so that the findings could be judged as to their reliability by the actual examination of the pancreas. These tests were carried out by Dr. J. L. Yates, then my chief assistant, whose large experience as a carefully trained laboratory investigator fitted him particularly for this task. He had, moreover, assisted me in the diagnosis, operation and after-treatment of a great number of cases belonging to this special group, so that he also possessed a large experience as clinical surgeon.

These tests were extremely fascinating, but it seemed to us that it required too much of the personal element of the observer to make the method useful except in the hands of unusually skilful experts.

The fact that surgeons like Robson and Moynihan continue to trust this test is, however, sufficiently important to convince me that it contains real merit.

SYMPTOMS

If we add to the well-known symptoms of cholecystitis an area of tenderness from 5 to 10 cm. long located to the right of the umbilicus over the middle of the right rectus abdominis muscle in cases in which we can exclude a diagnosis of duodenal ulcer we have the typical symptoms on which to make a diagnosis of pancreatitis.

In duodenal ulcers there are two symptoms usually present which are not symptoms of pancreatitis: (1) pain before meals when the stomach is empty and (2) hyperchlorhydria with eructation.

In pancreatitis there is frequently referred pain to the mid-scapular or left scapular regions. In gastric ulcer the same pain is commonly present, but with this there is pain on deep pressure at a point half-way between the ensiform appendix of the sternum and the umbilicus.

There are, of course, cases in which two or more or all of these conditions are present in the same patient and other cases in which it is possible only to determine the fact that one or more of these conditions are present, while a strict differential diagnosis may not be possible. In these cases, however, it is quite possible to determine the necessity of an exploratory incision, and, when the indications for this are not clear, then it is usually safe to keep the patient under dietetic treatment until further study of the case has cleared up the diagnosis.

Solomon[13] has pointed out the fact that in the presence of pancreatitis von Noorden's oatmeal diet gives rise to typical butter stools and that an abnormally large amount of lecithin is excreted. From 0.4 to 1.2 gm. is excreted in twenty-four hours when these patients are placed on an egg diet, while normal individuals excrete not to exceed 0.1 gm. under similar feeding.

According to Schlecht[14], Mueller's test is quite reliable. The patient is given a test meal which is followed after two hours by a calomel purge. A few drops of the stool are sterilized by heat, then placed on an agar plate containing Loeffer's serum. The plates are kept in an oven at 131 to 141 F. for twenty-four hours. If trypsin is present the serum shows pronounced depressions, if absent the surface is smooth. Lepine[15] has made most interesting but very complicated experiments which he claims are valuable in the diagnosis of this condition.

In advanced cases there is usually marked emaciation frequently with peculiar circumscribed areas of fat in roll-like masses on the front and sides of the chest and abdomen. There is usually marked anemia present, often approaching chlorosis with degeneration of the erythrocytes. Many of these patients suffer from obstinate constipation while others have equally troublesome diarrhea.

Sugar is present in only a small proportion of these cases.

TREATMENT OF CHRONIC PANCREATITIS

The treatment must consist primarily in relieving the irritation due to the backing up of infected bile by establishing free drainage which must be sufficiently permanent to permit complete restoration of gall-bladder and ducts as well as the pancreatic ducts. It is important to keep the intestines and stomach normal and free from irritation permanently by the use of proper diet and hygiene after these operations.

In case gall-stones or pancreas stones are present, these must be removed, whatever their location may be. In rare cases in which the common duct is permanently obstructed, cholecystenterostomy may be indicated.

It is probably best to make the anastomosis between the gall-bladder and duodenum where possible and between the gall-bladder and jejunum through an opening in the transverse mesocolon where the duodenum cannot be safely reached. The suture method should be employed similar to the one employed in posterior gastroenterostomy.

ACUTE PANCREATITIS

It is difficult to make a differential diagnosis in acute pancreatitis with any degree of certainty because there are several other violent acute conditions which are so similar in their symptoms that they can probably never be positively excluded. The conditions most likely to be confounded are (1) perforation of the posterior wall of the pyloric end of the stomach; (2) perforation or gangrene of the gall-bladder or duodenum.

Cases of severe acute pancreatitis have been diagnosed as acute intestinal obstruction, renal colic, ectopic gestation and, of course, appendicitis and gall-stone colic.

In acute pancreatitis the pain is extremely severe in the right upper quadrant of the abdomen. There is intense shock; nausea and vomiting are usually present and the patient gives the impression of being at the verge of destruction. The abdominal muscles are tense, although Moynihan[4] found this symptom absent in some of his cases. There is usually a steady rise of the pulse from the onset.

In these cases there is usually a history pointing to gall-stone colic in previous milder attacks (Fitz[16]).

If a tumor be felt there is usually tympanitis on percussion over this surface because the gland is located behind the duodenum (Elliott[17]).

Cyanosis has been observed by Opie and others. Sugar is present in the urine in some cases. Egdahl[5] gives a careful review of 107 cases in his study of the symptoms and diagnosis of acute pancreatitis which is well worth the careful consideration of the clinician.

SURGICAL TREATMENT OF CHRONIC PANCREATITIS

In chronic pancreatitis the treatment originally practiced and advised by Mayo Robson, consisting in the establishment of perfect drainage through a cholecystostomy opening, seems to be still the best. The edema of the common duct and the pressure and consequent obstruction due to the presence of an enlarged pancreas are thus relieved and with this the pancreas and the liver are simultaneously reduced to a normal size.

The portion of the gland that has been hopelessly destroyed is, of course, permanently lost, but the remaining portions are usually sufficient to perform the necessary physiologic functions if the patient is properly educated in the selection of food.

SURGICAL TREATMENT OF ACUTE PANCREATITIS

In mild cases of acute pancreatitis surgical treatment is not indicated. If the local irritation is removed by making gastric lavage and placing the patient on exclusively rectal alimentation so that nothing passes through the duodenum for a time the obstruction to drainage through the common duct will soon subside because of the disappearance of the local edema and then the conditions will be favorable for recovery from acute pancreatitis.

The correctness of this view must be plain to every one who has operated on a large number of patients suffering from acute gall-stone impaction in the common and cystic ducts at various periods during these attacks.

If an operation is performed during the attack the simple drainage of the gall-bladder has always, in my experience, sufficed to relieve the condition except in cases in which there existed at the same time a severe acute cholangeitis in which there has been a mortality of about 30 per cent. A moderate degree of cholangeitis will subside even if there is marked acute pancreatitis, provided the operation itself does not increase the infection.

It should be as simple as possible and no rough or unnecessary handling of the inflamed tissues should be employed.

Even in violent acute cases of pancreatitis a proportion of patients will recover if the abdomen is quickly opened and simple drainage is introduced. Glass tubes covered with gauze, split rubber tubes or cigarette drains may be employed. The number of recoveries depends on the severity of the attack and the promptness with which drainage is supplied. Robson has had nearly 40 per cent. of recoveries. Patients in whom the extravasation of pancreatic juice has caused fat necrosis are least likely to recover. I have seen several of these patients that have recovered without and one with operation and Mayo[18] reports similar results.

Unless jaundice is present it is best to limit the operation to the location and drainage of circumscribed areas of infection or necrosis of the pancreas, to the control of hemorrhage by means of fine catgut sutures and the free drainage of the entire area. This can best be done through a median or a high right rectus incision. It is *important to go over the gland carefully, but it is* quite as important not to traumatize the tissues unnecessarily. These patients have but a slight margin of possibility to recover and this can easily be lost by unnecessary traumatism or prolonged exposure.

If jaundice is present simple drainage of the gall-bladder with removal of loose gall-stones is indicated, but it is best not to interfere with stones impacted in the ducts. I have lost two patients needlessly before appreciating the folly of doing too much in these cases.

In a general way the following conclusions seem proper:

1. A clinical diagnosis of chronic pancreatitis is usually possible before operation.
2. This condition is practically always a complication of gall-bladder or gall-duct disease, except when following metastic infection.
3. It is usually curable by relieving the pathologic condition of the gall-bladder and ducts.
4. An operative diagnosis of acute pancreatitis can often be made.
5. Early operation greatly improves the prognosis.
6. It is important to reduce to a minimum the trauma in these cases.
7. The important factor in the treatment consists in the establishment of free drainage.

Importance of Tuberculides for Diagnosis of Tuberculosis in Infants.—*J. S. Leopole* found typical *papulo-squamous* tuberculides in 40 per cent. of 30 cases of tuberculosis in children less than a year old. In 5 of the cases they were the only sign of the disease and were thus a premonitory symptom of tuberculosis; in 2 cases they were the only means by which the tuberculosis was differentiated from syphilis. The arms, the lower part of the back and the back of the legs are the most frequent seat of the lesions; in *only* a few cases was there more than one. Such lesions are generally overlooked. He never found these typical lesions on children free from tuberculosis, and the tuberculin reaction or the later course of the disease confirmed their tuberculous nature. His article issues from Finkelstein's service at Berlin, and is published in the *Zeitschrift f. ärztliche Fortbildung*, Feb. 15, 1910.

NEWER METHODS OF DEMONSTRATING THE TREPONEMA PALLIDUM WITH ESPECIAL REFERENCE TO THE INDIA-INK METHOD*

FRASER B. GURD, B.A., M.D.
NEW ORLEANS

Since Schaudinn demonstrated the presence in syphilitic lesions of a spirillum which he called *Spirochæta pallida,* afterward changing the name to *Treponema pallidum* because the name *Spirochæta pallida* had already been given to another organism, numerous observers have attempted to utilize various methods in the hope of rendering the demonstration of the organisms more easy. Schaudinn made use of Giemsa's azur eosin polychrome mixture by which the organism is demonstrated as a pale slightly reddish-blue spiral. The various modifications of the Jenner or Romanowski stain have shown themselves of value, especially those of Leishman and Wright. The shortening, too, of the time necessary for the staining by Giemsa's method have increased the usefulness of this procedure although, perhaps, a less satisfactory stain results than when the original stain is used.

The identification of the organism, however, by all of these methods is far from easy and decidedly tiring to the eyes. Levaditi's method of demonstrating the organisms by the deposition of silver has proved itself invaluable, especially for the demonstration of the treponema in the tissues. Levaditi's method is, however, lengthy and not well adapted to general use by the practitioner of medicine.

The perfecting of the "dark-field" condenser has been a great boon to those of necessity examining numbers of specimens for diagnostic purposes. But what will probably prove to be the most valuable procedure to the practitioner at large on account of its simplicity, the cheapness of the materials used and the comparative ease of finding the organisms in the microscopic field, is that known as the "India-ink method."

I shall refer first to the "India-ink method" and later speak of the special advantage of the dark-field illumination in recognizing the differential characteristics of the spirochete. In 1909 Burri in his monograph drew attention to the fact that bacteria were not stained by India ink and that as a result the presence of micro-organisms in a thin layer of ink could be recognized by the presence of clear areas in a dark field. He advocated especially the addition of ink to growing cultures of organisms in order to watch cell division. Hech and Wilenko[1] in July, 1909, published the observation that the *Treponema pallidum* along with other micro-organisms, rendered itself easy of identification by this method.

The technic of the method is simplicity itself. As in procuring material for staining by any method the superficial necrotic layer, if it be an ulcerating surface, or the superficial epithelium, if the lesion be covered by epidermis, is scraped off and the serum which exudes is removed by means of a curette or scalpel. The fluid thus obtained is placed on a slide and an equal quantity of ink added. The ordinary commercial India inks may be used, Günther's being particularly good, although the results with Higgins' waterproof ink are good enough. The serum and the ink are then rapidly and thoroughly mixed and smeared over the slide so that a pale brown color results. The material dries in a minute or slightly more and is immediately ready for examination on placing the oil for immersion directly on the ink smear.

The picture produced will show the red blood-cells as large clear circular areas in a brownish-black field, the bacteria and débris present appearing as white rods and dots and spirochetes, if present, as clear white spirals. Hecht describes the appearance as being similar to that produced by dropping pieces of glass rods into a mixture of melted dark-colored agar in a Petri dish and holding it up to the light when cold. This description though somewhat clumsy, is sufficiently exact to give an idea of the general impression.

It is particularly important in using this method that in so far as possible serum alone be used and that a minimal amount of mucous material or fibrin be mixed with the ink. The presence of mucus results in its taking up a large amount of the color material of the ink, with the result that a smear of the requisite color and thickness cannot be made. If too much serum is used the albuminous material appears to precipitate the stain from the fluid and a finely granular appearance is seen microscopically, which is practically worthless for diagnostic purposes. Again, if too much ink is used the surface of the smear is increased in size to such an extent that the task of examining it thoroughly is greatly lengthened.

Regarding the reliability of this method perhaps it is not yet possible to speak definitely. It would appear, however, from my own results that here we have a method by which a definite diagnosis of syphilis is made possible in as great a number of cases as by any other microscopic method. A series of cases have been examined making use of this method and using Giemsa's and Wright's stains as controls. In every case in which either of the staining methods revealed the organisms the India-ink has demonstrated these in as large numbers and with a smaller expenditure of labor and time. True, the characteristic staining reaction of Giemsa's method is not present, but this loss is more than compensated for by the distinctness with which the morphology may be studied.

Practically only two or, perhaps, four organisms are apparently noteworthy in the differential diagnosis of the *Treponema pallidum* and in lesions elsewhere than the mouth and intestines only the *Spirochæta refringens* comes into thought. This organism, generally easy of differential diagnosis, by all methods, is particularly so when demonstrated by the ink method with its coarse body and broad curves.

In the mouth the *Spirochæta dentium,* the *Spirochæta buccalis* and the spirillum of Vincent may all be found. The presence of the latter along with the fusiform bacillus, together with the larger size and smaller number of its curves, renders confusion almost impossible. The *Spirochæta buccalis* too, with its morphology similar to that of the *S. refringens* is easily distinguished from the treponema with its short deep curve. The *Spirochæta dentium* is more liable to lead to error in diagnosis; its body is finer than the other forms mentioned and the curves shorter and placed more closely together. The body of this organism is, however, always definitely thicker than the treponema and never does one find more than five turns to the diameter of a red blood cell, nor are the extremities drawn out in the manner of the organism of syphilis.

Coles[2] notes a useful point in the diagnosis of the treponema, namely, that if the number of turns of the spiral of the *syphilitic spirochete* in the length of the diameter of a red blood cell be counted, these will be found to be from six to seven. The distance from the top of one spiral to the next is from 1 to 1.2 microns. The red blood cells measure about 7.5 in diameter so that on the average six or seven turns will be equal that of a red blood cell. The treponema varies in length from 6 to 15 microns or even more, and consequently contains from six to fourteen and sometimes twenty or more turns of the spiral. This measurement of the length of the spiral is usually possible, and is of the greatest value in identifying the treponema. The *S. dentium* rarely has more than four or occasionally five turns; the other organisms mentioned above from two to three, possibly five but never more.

---

[1] Hech and Wilenko: Wien. klin. Wchnschr., July 1, 1909, No. 26.

[2] Coles: Brit. Med. Jour., May 8, 1909.

For the absolute diagnosis, as mentioned above, the consideration of the motion of the live organism by means of the dark field is very important. Whereas the saprophytic spirilla, in addition to their different morphology, are actively motile and move across the microscopic field more or less readily, the treponema seems to lie lazily in the material in which it is suspended, swaying its body one way and then another, having at the same time a rotary motion, moving from time to time, too, a little backward or a little forward, but never changing its relative position very markedly.

We have then in the India-ink method a procedure of almost ridiculous simplicity which, if by the prolonged observations of competent workers, it is proved to be reliable, will be a means of putting the microscopic diagnosis of syphilis within the reach of all who have even a moderate knowledge of the use of the microscope.

PLUGGING NOSTRILS WITH COTTON AS PROTECTION AGAINST DISEASES CONTAGIOUS BY INHALATION

HENRY ALBERT, M.D.
IOWA CITY, IOWA

There is little doubt that the causative agents of most infectious diseases and especially those that are highly contagious enter the system by being inhaled, and invade the tissues primarily through the mucous membrane of the nose or other portions of the respiratory tract. Recent investigations have also proved that a person who has never had a certain disease may be a "carrier" of the germs of that disease otherwise than by the long recognized modes of carrying the bacteria about on hands, clothing, etc. For instance, a person exposed to diptheria may have his nasal cavity or throat infested with diphtheria bacilli even though not affected by the disease and such person may transmit the germs to another in whom the disease may develop.

The peculiar distribution of cases of epidemic cerebro-spinal meningitis and poliomyelitis, viz., the development of cases in different portions of a locality in individuals who have been in no way associated with each other, while at the same time persons directly exposed often remain unaffected—suggests, first that only a relatively small number of persons are susceptible to infection with these diseases, and, second, that the infective agent is carried about in the nasal cavity of individuals who are themselves not susceptible to the disease but in whom the germs may remain and multiply for a long time. Such indeed has been proved by bacteriologic examinations to be the case with the meningococcus. Association with a susceptible individual may cause the transmission of the disease. Inasmuch as drying readily destroys meningococci as well as other bacteria, or at least attentuates their virulence, it is much more probable that cases developing at long intervals of time may be better explained by coming from the nasal or buccal discharges of a carrier than from the clothing of a person exposed.

It would seem therefore that we should make a special effort to prevent pathogenic germs from being inhaled, both to protect ourselves from such germs and to prevent our becoming a "carrier." The efficacy of cotton as a bacterial filter is well known. That it is quite as efficacious for the nasal cavity as for a test-tube may be demonstrated by simple experiments. There would seem little reason why physicians and those nursing patients who have diseases which are contagious by inhalation should not protect themselves and others by placing a piece of cotton in their nostrils while in attendance on such patients.

EXPERIMENTAL POLIOMYELITIS IN MONKEYS

SEVENTH NOTE: ACTIVE IMMUNIZATION AND PASSIVE SERUM PROTECTION*

SIMON FLEXNER, M.D., and PAUL A. LEWIS, M.D.
NEW YORK

The experimental investigations of epidemic poliomyelitis, carried out during the past several months, have added a large number of important facts to the knowledge of this disease. These facts relate to the nature of the cause of the disease, the manner of its entrance into and exit from the body, the pathogenesis of the affection, and the existence of an enduring state of resistance to reinfection following an attack of the disease.[1] In the present communication we wish to present briefly certain further results which have been obtained in the course of experiments on active and passive immunization in respect to experimental poliomyelitis in monkeys.

The virus which we are employing in our experiments was derived from Case K,[2] is in its twenty-fifth generation in monkeys, and has attained a high degree of activity. Intracerebral inoculation of even minimal quantities of a filtrate[3] (0.02 to 0.01 c.c.) prepared from the spinal cord of a recently paralyzed animal causes almost invariably the development of paralysis within six to eight days. Recovery almost never takes place. This virus may, therefore, be regarded as of maximal potency.

ACTIVE IMMUNIZATION

With this virus we have endeavored to produce active immunity in monkeys and, in certain instances, successfully. The virus has been injected subcutaneously in gradually increasing doses over a period of several months, after which the immunity has been tested by a full intracerebral injection of the filtrate. An example is given.

Macacus rhesus. Inoculated daily from Jan. 12, 1910, to Jan. 16, 1910, with 0.05 c.c. suspension M.A. virus. Rest of four days. Inoculation from January 20 to January 23 with 0.05 c.c. virus. Rest of four days. Daily inoculation for four days with 0.1 c.c. virus. Rest. Inoculation of successively 0.1 c.c., 0.5 c.c. and 1 c.c. virus. On March 23, 1910, 5 c.c. of suspension of virus given. No visible effect produced by the virus. April 2, 1910, intracerebral injection of 2 c.c. filtrate of K virus. No effect. Animal in perfect health May 9, 1910. Control animals injected with 0.01 c.c. to 0.1 c.c. filtrate became paralyzed in average period.

---

* From the Laboratories of the Rockefeller Institute for Medical Research, New York.

[2] Flexner and Lewis: The Journal A. M. A., 1909, liii, 1913.

[3] Flexner and Lewis: The Journal A. M. A., 1909, liii, 2095

In the earlier experiments, before the virus had attained maximum activity, a small number of monkeys failed to develop paralysis after intracerebral injections of considerable amounts of unfiltered emulsions of the spinal cord from recently paralyzed animals. When these monkeys were tested subsequently with the more active virus they became paralyzed practically without exception. The unsuccessful inoculation does not appear to have increased markedly the natural resistance to infection. On the other hand, we have met instances in which monkeys have failed to react to the glycerinated virus later resisted successfully an intracerebral injection of as much as 2 c.c. of a filtrate of maximum potency. Glycerin may, therefore, modify, after some time, the virus and render it more suitable for purposes of immunization.

PASSIVE SERUM PROTECTION

We observed early that monkeys that recovered from the paralysis, either perfectly or with residues, were insusceptible to reinoculation with the virus; in other words, they had developed an artificial immunity. The question, therefore, arose as to whether the immunity principles existed in the blood in sufficient concentration to be capable, first, of neutralizing the virus *in vitro* and next, in the body of infected monkeys. The experiments to determine the former were made with the maximal K virus of which 2 c.c. of a filtrate were mixed with 2 c.c. of the serum of recovered cases, incubated for one hour at 37 C. and then placed in the refrigerator over night. This mixture failed to cause paralysis in *Macacus rhesus* when injected intracerebrally, although the control animals succumbed in the usual period. Normal monkey serum has no such restraining action.[4]

The successful outcome of this experiment suggested that the blood of persons who had recovered from poliomyelitis contained similar immunity principles.[5] The blood serum obtained from children through the kindness of Dr. Terriberry, was used for experiments. The monkeys having received the mixtures of filtrate and serum are still well, while the control animals have succumbed. Since, however, the incubation period, in rare cases, exceeds thirty days, the conclusion that the paralysis is prevented and not merely delayed, cannot be reached until the expiration of that period.

In contradistinction to these successful experiments is the failure to produce a neutralizing serum in the horse by repeated injections of filtrate. The horse serum, when mixed with the virulent filtrate and incubated as stated above, displayed no power whatever to inhibit the action of the virus. The monkeys injected with the mixture of horse serum and virus became paralyzed in the same average period as the controls.

The second series of experiments were conducted along two lines. One set of monkeys received intracerebral injections of the filtrate in doses varying from 0.1 to 0.01 c.c. in the afternoon. The next morning the serums from the monkeys and from the horse were injected into the subdural space and these injections were repeated daily or at somewhat longer intervals. We chose this mode of procedure for several reasons: First, we desired to ascertain whether the virus, once it was established in the body, could be restrained, because, if this proved possible, the outlook for some measure of control of the spontaneous disease in human beings might become hopeful. Second, we had already determined[6] that the virus, however introduced into the body, first establishes itself in the cerebrospinal meninges where it propagates and induces cellular changes and reactions to which the paralysis, etc., are indirectly due. It seemed rational, therefore, to endeavor to bring the neutralizing serum into direct relation with the virus by intraspinal injection. Next, it has already been determined in the case of epidemic cerebrospinal meningitis[7] that the serum quickly escapes from the subdural space into the blood, and hence, that if it were desired to maintain intimate contact of a serum with the meninges, daily injections must be made. It was believed furthermore that multiplication of the injected virus had already started in the interval between inoculation and injection of the serum and the serum probably would not suffice to destroy immediately all the organisms there present. Finally, we do not possess at present any definite knowledge concerning the injurious action of the virus on other important organs than the nervous system. If such action does occur and can be prevented by an immune serum, the results would probably be equally good whether the serum gained entrance into the general blood from the meninges or subcutaneous tissue. In the other set of monkeys the intranasal mode of inoculation of the virus was employed and the serum treatment instituted immediately afterward.

Before giving, in brief, the results of these experiments, which must still be regarded as of preliminary character, it should be stated that the immune serum obtained from the monkeys, which had recovered from paralysis, had in every instance been subjected to reinforcement by subsequent inoculations, often of large doses, of active virus. Whether any reinforcement is actually accomplished is still an undecided question; but judging from analogy, it should have taken place. The point is under examination.

The indications of our experiments along these lines are (1) that if the quantity of the virus injected into the brain eighteen to twenty-four hours before the serum treatment is begun is not in excess of a given dose, the action of the virus can be prevented; (2) that the infection of the meninges from the nasal mucosa can also be prevented by the serum injections; (3) that normal monkey serum has no such restraining effect; and (4) that the horse serum is entirely without preventive action and tends rather to hasten the onset of paralysis.

April 12, 1910: *Macacus rhesus*. Intracerebral inoculation of 0.01 c.c. filtrate virus K. April 13, 1910 to April 22, daily intraspinal injection of 3 c.c. immune serum. April 27, 1910: Injected 3 c.c. immune serum; May 2, 1910, repeated injection. Animal remains perfectly well.

In the case of the intranasal inoculations, the injections of serum were made immediately after infection was made and at three-day intervals for three injections. The control and the animal treated with horse serum succumbed and the animal treated with immune serum survived.

---

[4] Similar observations have been made by Römer and Joseph (München. med. Wchnschr., 1910, lvii, 568); and Levaditi and Landsteiner (Compt. rend. Soc. de biol., 1910, lxviii, 311), have reported such a neutralization experiment.

Experiments are in progress to determine whether the paralysis, after intracerebral inoculation, can be prevented by immune human serum and what the limits of the control of the experimental disease by such sera are. In considering these results and particularly their significance for human pathology, account should be taken of the fact that experimental poliomyelitis in monkeys is a far more severe and fatal disease than epidemic poliomyelitis in human beings.

In view of the fact that the virus of poliomyelitis can enter the nervous system through the abraded mucous membrane of the nose, we have tested the effects on the virus of hydrogen peroxid and some other disinfecting agents. The virus is quickly destroyed by a dilution of perhydrol containing 1 per cent. of hydrogen peroxid.

RAPID BLOODLESS CIRCUMCISION

OF MALE AND FEMALE AND ITS TECHNIC

S. L. KISTLER, M.D.
LOS ANGELES, CAL.

Circumcision, one of our most common minor operations, is bunglingly done in many instances, notwithstanding its simplicity.

This operation, though an old one, is still interesting and means have long been sought whereby it could be more easily and quickly performed and be attended with less hemorrhage, and consequently meet with less objection on the part of parent and patient.

Many a surgeon has lost his best clients, and likewise many a good prospect has gone glimmering because of the unfortunate outcome of this little operation.

The necessity for circumcision is abundantly evidenced, and although it may be needless to state any reasons for doing this operation, nevertheless I will mention a few:

1. Reduced tendency to convulsions in infancy arising from irritable nervous system.
2. Habit of masturbation not so likely to be formed.
3. Lessened irritability of child or adult.
4. Amorosity reduced.
5. A hygienic condition promoted.
6. Venereal diseases not so readily contracted, and consequently:
7. Fewer pelvic diseases in women.
8. For impotency in old men, as has been advocated.

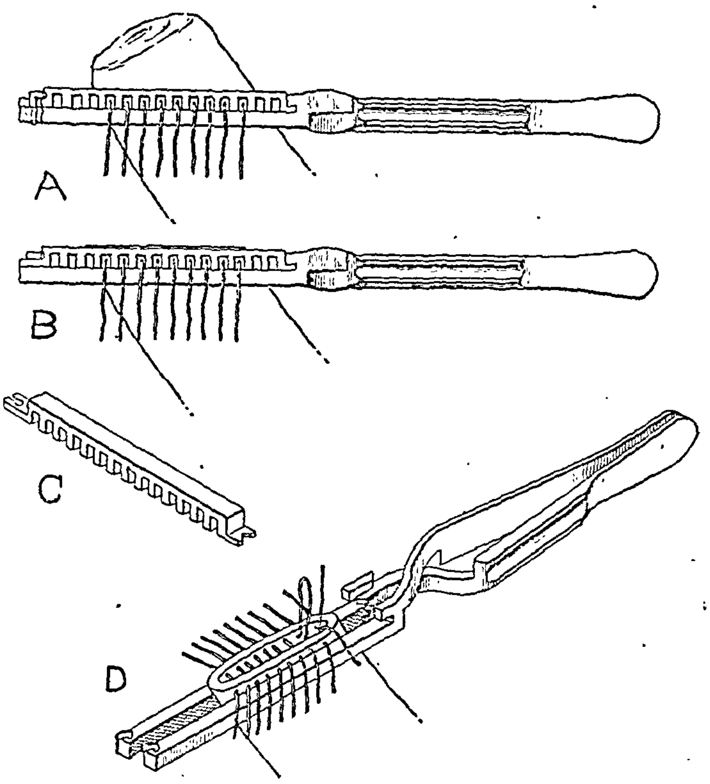
The ease with which this operation can be done by use of the instrument here described is so marked that a person could circumcize himself, provided he did not become faint-hearted. Only one-quarter of time required for other methods is needed. This operation is practically bloodless, as all ligatures are uniformly placed and tied before the clamp is removed.

The illustration shows clamp on and ligatures inserted (A); then the removal of the foreskin (B), and next, the removal of the upper sections of the blades (C), and two ligatures pulled up, one of which has been cut and is ready to be tied (D). The instrument has twelve slots or ports instead of fourteen as is shown in the illustration.

METHOD OF PROCEDURE

1. Use local or general anesthetic as deemed best.
2. Adjust clamp.
3. Insert sutures.
4. Excise foreskin with scissors or knife.
5. Remove upper section of each blade by releasing at distal extremity and lifting off.
6. Insert a ligature in anterior portion of foreskin in addition to those already inserted, if desired; also insert one posteriorly.
7. Pull each suture up singly, cut loop in center, tie each side as indicated, and having tied all ligatures, remove clamp and apply dressing.

If deemed expedient, spear the mucous membrane and draw out as desired before applying the clamp. If the foreskin adheres to glans, split on dorsal aspect to corona, break down adhesions, apply clamp and operate one side at a time, and, having no loops to pull, only skin and mucosa to unite, you can operate very rapidly. A young child may not always require stitches; however, I think it best to insert several, but each operator will use his own judgment in the matter. A better result will be obtained when the mucous membrane is cut long and the skin comparatively short, as is the case when this instrument is employed. There is practically no blood, no anxiety, no misgivings as to results, and the work is done quickly and easily. Frequently too much mucous membrane is removed and too little skin. Leave more mucous membrane and less skin and then an ideal result will be obtained.



Modified phimosis clamp, showing the manner of using it. A clamp applied, sutures placed; B, foreskin removed; C, removable section of blade; D, sutures ready to be tied.

Many females need circumcision, and the operation is more easily performed than in the male. The clamp is applied singly to such elongated or hypertrophied parts as it is desired to remove, ligatures inserted, part excised, upper part of blades removed, ligatures tied without necessity of pulling up loops, etc., clamp removed and dressing applied.

I have never tried this instrument for protruding pile tumors (of considerable length), but it occurs to me that a beautiful operation could be performed by its use, for the reason that double ligatures could be inserted through the vein posterior to the sacculated portion, and then the set of ligatures used for the vein could be withdrawn from the skin; thus the veins could be tied separately and the skin then closed with the other set of ligatures loosely tied, which would incidentally hold the vein in close contact with the skin.

Other phimosis clamps have been devised, such as those of Tortat, Levis and Skillern, but the advantage of my clamp and its distinctive feature is the notched, removable portion of the blades. This feature gives a smooth surface along which to remove the redundant tissue, leaving just the margin required to hold the stitches securely. The removal of these portions of the blades leaves the sutures free for rapid tying while the remainder of the clamp is still in place.

3146 Vermont Avenue.

HEMORRHAGE OF THE SPINAL CORD

H. W. RICE, M.D.
COLUMBIA, S. C.

Because of the rather unusual character of the injury I am constrained to report this case.

History of Injury.—In a scuffle between two women on a porch one was thrown, striking the back of her neck against the baluster rail. The rail gave way and she fell some four feet to the ground on her head. She was picked up helpless and carried to her room. A couple of hours afterward I saw her.

Examination.—Total paralysis existed below a line extending from the top of the shoulders across the chest about two inches below the clavicle. She could move her head from side to side, forward and backward movement being somewhat impaired. She could elevate the shoulders and clavicle only slightly. There was slight tenderness on pressure over the region of the fourth cervical vertebra. Otherwise the patient had no pain anywhere. No fracture or dislocation of the vertebræ could be made out, and the only surface injury was a bruise over the right frontal region. The tongue could be protruded straight. The face muscles acted symmetrically and there was no impairment of speech. The mind remained perfectly clear. The pupils reacted normally. There was no disturbance of any of the special sensations. The superficial and deep reflexes were lost in all parts of the paralyzed portion of the body. Voluntary control of the rectum and bladder was lost. The bladder emptied itself intermittently, perhaps from overdistention. The bowels remained constipated and did not respond to the strongest cathartics. Enemas served only to expel partially the gas of an extreme and persistent tympanitis. The pulse did not rise above 80, and the temperature remained under 100 F. throughout. Respiration was somewhat embarrassed at first, becoming more frequent and labored towards the last.

Diagnosis.—The lesion was decided to be hemorrhage of the cord, the approximate seat being determined by applying the principles of spinal localization as follows: The zone marking the paralyzed from the active segments of the body as indicated above was a line across the chest below the clavicle anteriorly and just above the spines of the scapulæ posteriorly. Motion and sensation existed everywhere above this line, and was lost everywhere below it. The groups of muscles represented by the sternomastoid anteriorly and the trapezius posteriorly were active as shown by the ability to move the head and neck in all directions and to slightly elevate the clavicle and shoulders. These muscles are innervated by the cervical plexus or four upper cervical nerves. The group of muscles next below represented by the deltoid, the biceps, and triceps were paralyzed as shown by the inability to move the arms or to completely raise the shoulders. These latter muscles receive their nerve-supply from the brachial plexus or four lower cervical segments of the cord, and therefore the hemorrhage must have extended as high as the zone between the cervical and brachial plexuses or as high as the fifth cervical nerve root. The spinal accessory nerve which in the main supplies the sternomastoid and trapezius muscles receives branches from the cervical nerves as low down as the third segment. Hence it was inferred that the lesion was somewhere below the third cervical nerve root. In short, the injury was probably between the third and sixth cervical nerve-roots. That the substance of the cord and not the membranes only was the seat of the hemorrhage was concluded from the following points: In hemorrhage of the membranes there would have been decided pain with a more gradual onset of paralysis; in meningeal hemorrhage we would expect to find the paralysis confined to one or more groups of muscles or involvement of one group after another until there was a complete paraplegia; in meningeal hemorrhage there is more apt to be a gradual improvement in the paralysis with possibly complete recovery; and in hemorrhage of the membranes inflammation is more likely to follow terminal meningitis.

Autopsy.—The patient died on the fourth day and the autopsy confirmed the diagnosis revealing the following conditions: There was a fracture without displacement of the tip of the spinous process of the fourth cervical vertebra, also a linear fracture of the left lamina of the fifth vertebra. A considerable amount of dark fluid blood exuded from the cervical tissues and a slight amount of extravasation was found in the dura around the fourth and fifth segments of the cord. A small amount of blood exuded from the subdural space. The central canal opposite the fourth, fifth and sixth segments contained minute blood-clots and macerated cord substance. There was a widespread ecchymosis of almost the entire cross-section of the cord at the level of these segments. The damaged section was limited between the fourth and sixth cervical nerve-roots.

The points in the case of special interest were the following:

1. The differential diagnosis between injury to the membranes and injury to the cord substance is important. In a purely meningeal hemorrhage the blood clot might be removed by a laminectomy, but if the cord substance is seriously involved surgical interference would be futile.

2. The deep reflexes below the seat of the lesion were lost while the automatic centers for the rectum and bladder remained intact; that voluntary control of the bladder and rectum was lost showing that the motor pathway from the brain to these organs was interrupted by the cervical injury.

3. The cause of death was probably paralysis of the phrenic nerve and was not immediate because not all the nerve origin was first impaired.

1316 Washington Street.

A CASE OF PELLAGRA IN ILLINOIS

J. H. BACON, M.D.
PEORIA, ILL.

As spring is the time of the year in which pellagra is most prevalent, and as all cases previously reported from Illinois have been asylum cases, the report of a case of that disease in private practice should prove of interest.

History.—I was called to see a woman, aged 37, who complained that she had been burned while taking a vaginal douche on March 30, 1910. She was a middle-aged woman, with a peculiar, dejected, staring expression, confined to her bed. Her family history was negative. She had been healthy as a child; was married; had five healthy children; had lived in Peoria last 20 years; had been constipated in childhood; always a light eater, rarely using meats. Her dietary was that of the ordinary laboring family; corn-meal mush served once a week; other corn products used frequently. She had suffered from a puerperal infection after the birth of her first child and had been in poor health since. In February, 1903, her last child lost twenty pounds in last five years. During 1905 she had a paralysis, of short duration, of the left arm and side of the face.

Present Illness.—In March, 1903, a rash appeared on the backs of both hands that persisted until the following winter. It came on as large blebs that became ulcerated at the base.

Her general health declined and menstruation disappeared entirely. Each following spring, usually in March, the eruption has reappeared, but dryer, more widespread and of a brownish-black color. These lesions have burned and itched, and sometimes have been quite painful, requiring morphin. During the eruption of 1907 a severe dysentery developed which has since persisted with from three to twelve stools a day. The eruption of 1909 covered forearms, hands, neck, feet and areas of the chest. Blebs under the eyes were lanced. The skin resembled elephant skin and frightened the children at times. The present attack began apparently after a vaginal douche when she thought she was scalded. Her mouth was sore, and the saliva hot and burning. Micturition was frequent and scalding. There were four watery stools daily. Her appetite was poor and she lost twenty pounds in last five years. During 1905 she had a paralysis, of short duration, of the left arm and side of the face.

Present Condition.—A small, emaciated woman, confined to bed, with a facial expression of despair; eyes prominent and reddened from weeping; complains of headache and loss of sleep; words are spoken slowly—in a drawl; lips large, protruding and cyanotic. The mucous membrane of the mouth is eroded in patches; the tongue is thick and the papillæ prominent; gums swollen, boggy, with pus exuding around the teeth; profuse watery discharge from nose and mouth; occasional cough; mucous expectoration; breath has foul odor. On sitting she becomes flushed and exhausted. Her feet drag and she settles to the floor on attempting to walk. There is no ataxia. The patellar reflexes are exaggerated. Babinski present. Her mental condition is clouded, memory poor and she is quite despondent. She has a chronic tuberculosis. The abdomen is tender, especially in the epigastrium. The external genitalia are excoriated; the skin is a brownish color, dry and scaly, with tendency to crack. There is no weeping. This condition is especially marked on both forearms and has well-marked outlines at wrists on flexor surface. The skin on the areas affected last year is thin and parchment-like. Urine is negative; stool is liquid, of a brown color, and foul odor. Numerous motile spirilla found. No ameba. Blood: Hemoglobin, 80 per cent.; reds, 4,000,000; leucocytes, 10,000; differential negative; no malarial parasites found.

Diagnosis.—The diagnosis seems clear, with recurring skin lesions for seven springs, improving in cold weather, the parchment-like skin, the dysentery and indigestion, the gastro-enteritis, the stomatitis, the thickened tongue, the relatively high hemoglobin, the impaired mental condition and the malnutrition.

Treatment.—The skin condition has improved under the use of an ointment containing boric acid and salicylic acid. The general condition has improved slightly with improved diet and the administration of iron, arsenic and strychnin. Headache and pain have required morphin.

HOOKWORM DISEASE IN KANSAS

K. B. FORD, M.D.
WICHITA, KAN.

My purpose is to call the attention of the profession in the northern states to the importance of being on the lookout for cases of hookworm disease. It is known that its natural geographical distribution is in the South and its practically complete absence in the North might cause it to be overlooked or diagnosed as one of the numerous other things, such as neurasthenia, which it so much resembles

While traveling in the southern states in September, 1909, through the courtesy of physicians in several places and at one medical meeting I had the privilege of seeing and examining several cases of hookworm disease and the adult worms, and of witnessing a microscopic demonstration of the ova. The knowledge of this disease thus acquired suggested the correct diagnosis in the following case:

History.—In April, 1910, a married woman, aged 32, consulted me, complaining of a gradual decline in strength, lack of energy and ambition and gave a list of symptoms that sounded like a treatise on the symptomatology of hookworm disease. The decline had been gradual, following a trip through the southern states and extending over a period of a couple of months. The patient did not feel ill but was tired out. She said that she had lost little, if any, weight.

Examination and Treatment.—The patient appeared to be well nourished, but had the sallow skin, the milky blue eye, and the anxious, tired, worn look of the hookworm victim. There was a patch of dermatitis on the anterior and external surfaces of the right leg, which the patient said had been there for two months. After a cathartic, and a fast, the patient was given thymol, followed by salines; the stools were examined with the assistance of Dr. Phares and the adult worms and ova were found in large numbers. The patch of dermatitis on the leg began to clear up after the first treatment. The depletion caused by the salines revealed the fact that the plump appearance of the patient was due to a general edema, which concealed a really marked emaciation.

Since having this experience I recall a patient, a young woman from Tennessee, whom I saw in August, 1909. She complained of indefinite pains, nervous symptoms, etc., no doubt due to the same cause, which was unsuspected at that time. Though these cases probably are rare in the North, it is evident from the above that the infection may exist in individuals coming from the South, or may be acquired by persons visiting that section even for a short time, and the possibility should be kept in mind.

1223 South Lawrence Avenue.

VARICELLA AS A CAUSE OF NEPHRITIS

REPORT OF TWO CASES

E. J. G. BEARDSLEY, M.D.
Chief of Outpatient Medical Department, Jefferson Medical College
PHILADELPHIA

The rarity of published accounts of nephritis complicating or following an attack of varicella indicates either that the associated conditions are infrequently encountered or that such cases are not reported by those observing them. It is well known that varicella is, in the majority of instances, a mild disease and free from serious dangers but occasionally the disease may be unusually severe or a complication or complications may lead to unfortunate results. When such complications are encountered it seems well to publish the account of the cases that others may profit.

Among the rare complications of varicella is nephritis. Henoch[1] first called the attention of the profession to this complication of the disease and published the accounts of four cases studied by him. Von Jurgensen,[2] Brunner,[3] Rille,[4] Dillon Brown,[5] Hogyes,[6] Janssen[7] and Oppenheim[8] have reported similar cases. I have had the opportunity of studying two cases which exhibited well-marked nephritis during and after an attack of varicella and in which there seemed good reasons for believing that the kidney affection was the result of the primary exanthematous disease. The following case has been previously quoted.[9]

---

1. Henoch: Berl. klin. Wchnschr., Jan. 14, 1884, No. 2.
2. Von Jurgensen: *Quoted* in Nothnagel's Specielle Pathologie und Therapie, 1896, iv, 294.
3. Brunner: Quoted by Brown in Twentieth Century Practice, xiv, 197.
4. Rille: Deutsch. med. Wchnschr., 1891, xvii, 301.
5. Brown, Dillon: Twentieth Century Practice, xiv, 197.
6. Hogyes: Jahrb. f. Kinderh., new series, xxiii, 337.
7. Janssen: Berl. klin. Wchnschr., 1887, xxiv.
8. Oppenheim: Berl. klin. Wchnschr., Dec. 26, 1887.
9. Hare and Beardsley: Typhoid Fever and the Exanthemata. Edition 2, 381.

CASE 1.—*History.*—The patient was an Italian girl, aged 6. The parents stated that, with the exception of a slight attack of bronchitis when 2 years of age, their daughter had never been sick. The illness began two days before the patient was seen by me. The child seemed "feverish" and complained of headache. During the evening of the day the symptoms appeared the mother discovered the skin eruption, which she described as being "warts with water in them." Two days following the appearance of the eruption the family noticed that the patient "was not right in her head" and sent to the dispensary for a physician.

Examination.—There were forty or fifty varicellous lesions scattered well over the chest, abdomen and back, with a few on the extremities. The temperature was 103.2 F. and the pulse 150. The lungs were resonant on percussion and the breath-sounds, although exaggerated, revealed no further abnormality. The patient was slightly delirious, the breath foul and the tongue thickly coated. The mother stated, on inquiry, that the child had not urinated for eighteen hours and that at the time the last urine was passed it resembled blood. The patient was placed in a hot pack, which soon relieved the delirium, and was later thoroughly purged. The first urine passed was not collected, but a specimen obtained a few hours later was very highly colored, and contained 1.2 gm. of albumin (Esbach's test) and large numbers of coarsely granular casts, many finely granular, a few hyaline casts and a considerable number of red blood cells; specific gravity 1026.

Course of Disease.—The day following the first urine examination the child was still slightly delirious and the urinary changes were much the same as before but a larger amount of urine was passed (10 ounces were collected). The casts remained in evidence for six days, after which time they gradually disappeared. The albumin persisted in the urine for two weeks, and then disappeared. Following this illness the child's urine was examined once a week because of her extreme pallor, but no abnormality was discovered for some time. Some six weeks after the initial illness the child was brought to the dispensary to be treated for "stomach trouble." The mother stated that since the illness there was evidence of a "weak stomach" while previously the child could eat any food with impunity. The pallor associated with the history of nausea and occasional attacks in which the patient vomited prompted me to examine her urine again. At this time there was found 0.5 gm. of albumin to the liter with many finely granular and few hyaline casts. This case was studied about one year ago and during the past year I have seen the child four or five times at intervals of several months for what the mother terms "stomach trouble." At each examination of the urine the nephritic condition has been evident. As long as the child is bathed and the diet supervised she remains in fairly good health, but if the vigilance of the inspecting nurse is relaxed and the family becomes careless, the child soon develops toxemic symptoms.

CASE 2.—*History.*—The patient was a colored boy, aged 5. The attack of varicella differed from that in the first case mentioned, in being much more severe, many of the lesions showing petechial hemorrhages. This child was taken suddenly ill with a slight convulsion and later vomited freely.

Examinations.—When the child was seen the skin was well spotted with vesicles. The temperature was 103 and the pulse 140. The lungs were clear but the throat was much inflamed. Two days after the rash first appeared many of the vesicles showed hemorrhagic tendencies and the child appeared stuporous. After considerable difficulty a specimen of urine was obtained but not until several days after the child had greatly improved under eliminative treatment. The urine was highly albuminous and contained granular, hyalo-granular and hyaline casts in large numbers. Two weeks later there was no albumin present in the urine but a few hyaline casts were found.

Course of Disease.—The urine was examined again six weeks after the initial illness and no abnormality found, but three months later the child developed a frank lobar pneumonia, became very toxemic and an examination of the urine presented the picture of an acute toxic nephritis. Three weeks after convalescence from the pneumonia, casts and albumin were still present in the urine.

From these cases and from the cases quoted from the literature it appears that the kidney structure may be seriously affected by varicella and the necessity of frequent urine examinations during and following even mild attacks of the disease is realized.

2030 Chestnut Street.

A DEATH UNDER ANESTHESIA DUE TO STATUS LYMPHATICUS

ERNEST B. BRADLEY, M.D.
LEXINGTON, KY.

Patient.—A boy, aged 7, with the following history: Whooping-cough with good recovery at the age of 2 years. No other diseases of childhood. Operation for enlarged tonsils and adenoids, by Dr. J. A. Stucky, three months previously. At this time patient took the anesthetic fairly well except for a slight accumulation of mucus in the throat which, however, was not particularly troublesome. There was no history of any kind of asthma, any difficulty there had been in breathing being entirely relieved by the removal of the adenoids.

Present Illness.—For the past three years the glands on the left side of the neck had been noticeably enlarged. They had increased in size rather markedly in the last few months, although their growth had not been uniform from the beginning. Dr. S. B. Marks, who had charge of the case, said that six months previously these glands seemed to become smaller, but on the whole they had grown, until at the time of examination they showed as a marked swelling from the mastoid process to the border of the first rib. At times there had been some temperature disturbance but as this usually disappeared promptly under a dose of calomel, it was supposed that it was due to intestinal ailments. The physical examination showed no other glands palpable; the chest and abdomen were apparently normal. The probable diagnosis of tuberculous glands was made by Dr. Marks, and this was concurred in by Dr. A. H. Barkley, to whom the case was referred for operation. On March 15 the author was asked by Dr. Barkley to administer the anesthetic at the operation for the removal of these glands.

Operation and Anesthesia.—As the child was crying and fighting, chloroform was used to begin; it took only a few whiffs to quiet him. Ether was then substituted and was used exclusively from this time on. Dr. Barkley removed the enlarged glands easily and practically without the loss of a teaspoonful of blood. The patient behaved well under the anesthetic, the only untoward symptom being that too much mucus would accumulate in the throat. This was never excessive, however, and on withdrawal of the anesthetic it disappeared. The pupils were at no time dilated and while never down to the pin-point, often seen, were always well contracted. After the anesthesia had continued for an hour and a quarter, when the surgeon had almost finished the operation, the mucus in the throat becoming somewhat troublesome, the patient was allowed to come out so that he might swallow. The cone was removed for about three minutes, when the winking reflex becoming very active, a few drops of ether were poured on the cone and this placed over his face. He took two or three gasps without getting any air into his lungs. The surgeon was informed and artificial respiration immediately resorted to. The sphincter ani was divulsed, the heart massaged by Dr. Marks, who was assisting, the throat cleansed of mucus, and the tongue pulled forward rhythmically. The heart could not be felt to beat and the pupils from being contracted dilated to full size. The patient's color was good and not the least cyanotic, showing that the heart and respiration must have ceased almost simultaneously. The efforts at artificial respiration were abandoned after fifteen minutes, during which time the patient was not induced to take a single breath.

Permission for complete autopsy could not be obtained but we were allowed to remove the thymus, which was found to occupy its usual position behind the sternum. It showed two lobes with a centrally placed isthmus and measured 5 cm. long by 4 cm. wide by 1 cm. thick. It weighed 9 gm. The fifty or more lymph-nodes taken from the neck had a total weight of 92 gm. They ranged from the size of a small pea to that of a small English walnut. On section they were firm and showed no softening.

Pathologic Report.—Sections of the thymus and of two of the larger lymph-nodes were sent to Dr. Aldred Scott Warthin, of Ann Arbor, who reported as follows: "As far as I can make out from the slide of thymus, it does not show any special change beyond that of a general hyperplasia. The lymph-nodes are extremely hyperplastic, and may be taken as representing the early stages of a lymphatic struma. There is no tuberculosis in the ones sent, and I think that the diagnosis of status lymphaticus is justified by the sections. There is certainly a marked lymphoid hyperplasia. The preservation of the germ centers in the lymph-glands rules out lymphosarcoma, and the condition is more typical of status lymphaticus than of Hodgkin's disease, though I believe that there is no hard and fixed line between some of the cases of Hodgkin's and those showing the clinical appearance of lymphatic struma."

146 Market Street.

RARE FETAL MONSTROSITY

ENTIRE ABSENCE OF ABDOMINAL PARIETES; TALIPES CALCANEOVARUS; SPINA BIFIDA

HARRY ARANOW, M.D.
Adjunct Gynecologist, Lebanon Hospital; Assistant Gynecologist, Presbyterian Hospital Dispensary
NEW YORK

While a number of cases of celosoma are reported in medical literature, I could find only one case in which the entire abdominal parietes were wanting.[1]

History.—Family history was negative; the mother was a primipara. I was called at about 2 a. m., Dec. 2, 1908. The patient had been in actual labor for about six hours and had passed a clot about five hours previously. Pains were occurring every five minutes. The abdomen was symmetrically enlarged. The fetal back was to right; the fetal extremities occupied upper left quadrant. The anterior shoulder was near middle line, and the fetal head was in the pelvis. Fetal heart sounds were heard in the right lower quadrant—142. The cervix was fully dilated. Position was R. O. A. I ruptured the membranes before removing the examining hand from the vagina. About 3 a. m., the head appeared at the vulva. Soon after, in the interval of pains, there were repeated gushes of blood from the vagina. I suspected a premature detachment of placenta but as the labor was progressing satisfactorily and the patient seemed in perfect condition, I did not interfere. After delivery of the head there was considerable delay in the birth of the shoulders. The hemorrhage continuing, I assisted the delivery of shoulders with fingers in the axilla. Even after the delivery of the shoulders, however, the body seemed to recede and to remain stationary. Slight traction brought fetus and placenta *en masse.*

Description of Child.—The head, neck and arms, pelvis, thighs and legs were perfectly formed. Both ankles were in position of talipes calcaneovarus. There was a small meningocele at the base of the sacrum. The abdominal parietes were entirely wanting and were replaced by a thin, transparent serous membrane. This membrane was continuous with both skin and parietal peritoneum at the costal and pelvic margins and along the outer border of the muscles of the back. This membrane also lined the inner surface (fetal) of the placenta and extended over the three blood-vessels near the center of the placenta. The umbilical arteries, the umbilical vein, the liver, gall bladder, stomach, intestines and upper part of bladder were plainly visible. With the exception of a low position of the transverse colon, an apparent shortening of the colon, a positive shortening and thickening of the omentum, all abdominal and pelvic (female) organs seemed to be normal. The child cried lustily but gradually grew weaker and died after about half an hour.

185 East Seventy-first street.

Therapeutics

HOW AND WHEN SHALL DRUGS BE ADMINISTERED?

This is a question of vital importance, as even if the diagnosis is correct, the indication for a drug positive, and the selection of the drug needed accurate, all is of no avail if the drug is administered in an insoluble preparation, at a wrong time to accomplish the object aimed at, or in a frequency that is either useless on the one hand or dangerous on the other. To be more explicit, it lacks physiologic and therapeutic sense to administer a drug, that is quickly absorbed and quickly eliminated, when a continuous action is desired, so infrequently that there is only momentary, intermittent effect. On the other hand, it is futile to administer a drug for immediate need that requires hours to act. It is certainly physiologically wrong to administer a drug frequently that requires hours, or even a day or two to be excreted.

The greatest number of mistakes in medication are made in the treatment of inflammations and diseases of the stomach, and in disturbances of the digestion. If simple gastritis is diagnosed, and it is decided to treat it with bismuth, how futile to expect that a few grains given immediately before meals (or, we are sorry to say, often immediately after meals) could do any good in ameliorating the irritation of the stomach mucous membrane. For bismuth to aid in healing this membrane, it must be spread well over it when the stomach is empty. Also, it is well to wash off the mucus which must of necessity form on any inflamed mucous membrane. Bismuth for this purpose should be given an hour before a meal, in a dose of 2.0 or 3.0 grams (30 or 45 grains), taken with a not too large amount of water, and such administration should be preceded a half hour before by a large draught of hot water, with or without a little salt, and perhaps a small amount of bicarbonate of sodium to wash off the mucus and prepare the membrane for the bismuth treatment. Such treatment once a day, combined with a diet regulated to cause the least irritation and the proper treatment of coincident constipation, will rapidly heal simple gastritis. This same treatment is a valuable aid in healing an ulcer of the stomach.

If it is deemed advisable to administer nitrate of silver, how useless, in the first place, to order it in such a form that it will be oxidized before it is taken by the patient, and how useless to give it after a meal. Also, what lack of good sense is displayed when a nitrate of silver treatment is given two or three times a day. How many would touch a canker sore, or other surface inflammation, with nitrate of silver three times a day, or twice a day, or even once a day? A nitrate of silver treatment for ulcer of the stomach or duodenum may be tried once a day, or once in two days, for a few days, but never for any length of time, and then it is best to have the dose of nitrate of silver combined with some inert earth, in capsule, and the capsule uncapped at the moment of swallowing and taken into the empty stomach with a suitable amount of hot water. This will insure, as near as it is possible, an application of the nitrate of silver to the ulcer.

The value of digestants as generally administered is open to much question. A small amount of pepsin, given after an ordinary meal, is probably of but little value. The value of dilute hydrochloric acid after meals, when the stomach needs it, is proved, and frequently when pepsin is administered it is combined with hydrochloric acid, and it is likely that the hydrochloric acid does the work. A combination of pepsin with bicarbonate of sodium, as often seen, is of course absurd. The coincident administration of pancreatin and pepsin seems unworthy of serious consideration. The pancreatin will not act in acid media, and its activity will doubtless be entirely destroyed before it reaches the intestine. Sometimes it may be advisable to administer bicarbonate of sodium before meals. At this time it may do two things. It may cause the contents of the stomach to be alkaline or neutral longer than without it, thus aiding the starch digestion due to the saliva. If, however, it is in the stomach many minutes before the meal, it would probably quickly stimulate an outpouring of hydrochloric acid to neutralize it. After meals it would doubtless prolong the starch digestion, and temporarily, at least, inhibit the protein digestion. For heart burn or pyrosis occurring several hours after a meal the bicarbonate of sodium is certainly valuable symptomatic treatment to counteract the hyperacidity. Such acidity, however, is often due to lactic acid and not to hydrochloric acid. Such treatment is purely symptomatic, and the repeated administration of soda is inadvisable, and the cause of the condition should be removed if possible.

A large number of drugs, especially alkaloids, even bitters, and alcoholic preparations in any amount, will inhibit the digestion more or less. In ordinary doses, however, the inhibition is probably but slight, and any drug or preparation that is irritant to the stomach should certainly be administered either directly, or within an hour, after meals. Even bland, non-irritating tablets, pills, and capsules should generally be administered after a meal, or at least with a large draught of water, and the tablets should be crushed before swallowing. Potassium chlorate tablets should not be dissolved in the mouth, as the concentrated saliva containing this solution when swallowed, is irritant to the stomach and may cause inflammation and even ulceration. Certainly such tablets should never be swallowed into the stomach, and there is no logical or rational reason for ever administering potassium chlorate internally. Bromid tablets, salicylic acid or its salts in tablets, tablets containing ammonium chlorid, and in fact most tablets may cause irritation of the part of the mucous membrane on which they dissolve, if swallowed into the empty stomach, and most of the above-named tablets should be predissolved, or certainly crushed before taking into the stomach at any time. Quinin pills or tablets should never be taken on an empty stomach. If in any dose other than a small tonic one, quinin will slow peptic digestion. Consequently, if large doses are administered, it is well to give them between meals, swallowed with a few ounces, more or less, of milk or other simple, easily digestible food. If a patient does not sleep well, or does not get to sleep readily at night, the possibility of a tonic capsule or pill of quinin, or quinin and strychnin, or strychnin, given after the evening meal being the cause of it should be considered, and the evening dose omitted. Also, many a patient is given hypnotics for insomnia, when the omission of the evening tea or coffee will allow normal sleep. It is physiologically wrong to give a hypnotic to a patient who is ill when he is being hyperstimulated by strychnin throughout the afternoon and evening.

For medication of the bowels with bismuth, large doses, or perhaps better, frequent doses, are always needed, as doses unless very large, given at long distances apart, are likely to pass along with the food and not medicate the bowel mucous membrane at all. It is useless to expect that bismuth administered by the mouth will heal or medicate the mucous membrane of the colon.

If morphin must be administered and the patient is taking nutriment, if possible, it should not be given within one or two hours after a meal, as the digestion will certainly be inhibited.

When cathartics are necessary, it is generally well understood which act rapidly and which slowly, which are to be given at bedtime or better even, often at suppertime for action the next morning, and which given before breakfast for immediate action. However, many combinations are made which combine quickly acting cathartics with slowly acting cathartics. Such combinations are certainly a mistake. Aloin, cascara, podophyllin, euonymus, sulphur, calomel, and rhubarb all generally act slowly, taking anywhere from 6 to 12 hours. The salines and the drastic cathartics generally act in from 2 to 4 hours. Senna may act in from 4 to 6 hours. Of course the size of the dose has a great deal to do with the rapidity of action, but the above is approximate.

It has been supposed for some time that the experiments were conclusive that saline purgatives acted by the fact that they were very slowly absorbed and caused an exudate of water into the intestine so that the fluid in the intestines and the fluid in the blood vessels would become isotonic, and that this mechanical fact, *viz.*, the water with increased peristalsis, was the cause of the large watery stools from salines. Clinically, it has also been noted that salines act better when the patient is up and about than when he is in bed and at rest. This has again seemed to prove that gravity had a great deal to do with the rapidity of the saline catharsis. Lately, however, Dr. Arthur F. Hertz, Assistant Physician at Guy's Hospital, London (*Guy's Hospital Reports*, Vol. LXIII) has shown, by administering bismuth preparations at various periods of digestion and taking *x*-ray pictures of the abdomen at different periods of digestion, that salines are really absorbed from the stomach and upper bowel and probably re-excreted into the lower intestine. Hertz, in cooperation with F. Cook and E. G. Schlesinger, has shown that when food is taken into the stomach it reaches the cecum in about four hours. A saline aperient, on the other hand, may cause an action of the bowels in some instances in even half an hour, and often within two hours. Insoluble bismuth being administered with a meal will show, by radiographs, the exact length of time in which food passes down through the different parts of the intestine. A seidlitz powder or its equivalent, taken at the time of the bismuth, or with the bismuth and food, and then radiographs taken, shows that the movement of the bowels comes long before the bismuth and food reach the cecum and colon. The excess of water excreted, therefore, with such movements cannot come from the small intestine, as otherwise it would wash the meal and the bismuth down with it, but really must be excreted into the lower gut. Saline purgatives also seem to cause no increased acceleration of the passage of the food from the stomach to the cecum. These investigations seem to show clinically that when it is desired to empty the colon and not act on the small intestine, salines are indicated, but when it is desired to cause stimulation for excretion or for increased peristalsis or for drainage of the upper intestine, other cathartics than salines are indicated.

Dr. William Brady, of Elmira, N. Y. (*New York Medical Journal,* Jan. 29, 1910) writes a most instructive article on the administration of drugs. He emphasizes the necessity of knowing the length of time before a drug is absorbed and about the length of time in which it will be eliminated.

Probably in no branch of medicinal therapeutics are more mistakes made than in the treatment of cardiac and circulatory weakness. Brady shows how really futile it is to expect active aid from digitalis in any acute heart weakness, and yet digitalin is constantly used hypodermatically for this purpose. Much of the digitalin on the market is unreliable, and while it is less irritant when used hypodermatically than the liquid preparations of digitalis, it has not been proved that it is any more effectual as a cardiac tonic than a sufficient dose of a liquid preparation of the whole drug. If the cardiac drugs are separated into cardiac stimulants and cardiac tonics (the stimulants acting quickly, but such action not lasting any length of time; the tonics acting slowly, but projecting their activities for a considerable length of time) one will not make mistakes in their use. The cardiac stimulants are, ammonia, camphor, strychnin, atropin, suprarenal and pituitary preparations properly used, and in some instances where only a quickly acting and not lasting stimulation is required, alcohol. The cardiac and circulatory tonics are, digitalis, strophanthus, caffein, and ergot used hypodermatically. Caffein and strychnin are really stimulotonics, both acting rather quickly and having their effects last a considerable length of time. In certain conditions when the heart is failing and the blood-pressure high, nitroglycerin and nitrites will relieve the heart and improve the whole character of the circulation. While nitrites act quickly and such action is theoretically and laboratorily quickly over, if given three or four times a day they will positively project, in most instances, a lowering of the blood pressure over the whole twenty-four hours.

Brady repudiates the so-called Da Costa (nitroglycerin compound) tablet containing digitalis, strophanthus, belladonna, and nitroglycerin, as combining drugs which act quickly with those which act slowly. His criticism is just. At the same time, the nitroglycerin of the second and third dose will doubtless prevent some of the vasomotor contraction of the first dose of digitalis. Consequently, the combined treatment, whether given in one tablet or in separate preparations, is often not bad therapy. Theoretically and practically a little more careful discrimination of the needs of each patient will develop a method of drug administration that will be satisfactory and yet will not require such combination, *viz.,* if the patient needs nitroglycerin, he probably does not need digitalis. On the other hand, if he needs digitalis, and it is inadvisable to contract the blood vessels, a small dose of digitalis may give satisfactory action, and nitroglycerin will not be needed.

Brady emphasizes the well-known but often disregarded fact that oils inhibit digestion by diminishing the secretion of hydrochloric acid. Consequently, if it is advisable to give a patient olive oil or cod-liver oil (and, as urged by Brady, pure, clean cod-liver oil acts just as well and often better than any emulsion), theoretically it should be given two hours after a meal, at about the time when the stomach will completely evacuate its contents into the duodenum. This is theory, and perhaps physiologically correct. Practically, it is very disagreeable for a patient to take oil two hours after meals, even if he were so daily situated as to be able to do so. Also, the contents of the stomach do not all pour, at one stated time, into the duodenum, but more or less frequently during the process of gastric digestion certain amounts are passed into the duodenum, and the oil might be passed into the intestine long before the gastric digestion was completed.

Brady states that hexamethylenamina is eliminated into the cerebrospinal fluid in one-half hour after its administration, and this, he states, in sufficient amount to inhibit staphylococcus growth. So far as we know, hexamethylenamina is harmless when administered in any ordinary amounts for most any length of time; consequently, the drug seems indicated whenever meningitis is present or is likely to develop. This drug is also eliminated and acts satisfactorily in inflammations of the gall-bladder and in inflammations of the urinary tract, especially of the pelvis of the kidney. It would seem advisable to administer it in typhoid fever to prevent localizations of the typhoid bacillus in parts of the body other than the intestine.

As Brady emphasizes, it should not be forgotten that the iodids are absorbed rapidly and are eliminated rapidly, unless they have been given for a long time, when it may take several days for the excess of iodid to be completely eliminated. Bromids, on the other hand, are absorbed rather slowly and are eliminated very slowly, and if taken for a long time, may not be completely eliminated for weeks.

Phenolphthalein is very slowly absorbed and acts very slowly and is best given as a tablet which should be thoroughly masticated before swallowing. Sometimes this drug, even in small doses, causes a great deal of irritation of the bowels.

Thyroid Treatment of Regularly Intermittent Joint Effusions.—P. Ribierre gives a historical sketch of regularly intermittent joint effusions, the syndrome, differentiation, etc., and reports a typical case in which analysis of the attacks, their periodical recurrence and the general condition suggested that the thyroid functioning might be at fault. The subsidence of the attacks during pregnancy and various other features of the disease sustain the assumption of defective glandular functioning as the main factor in the etiology, he is convinced. His patient was a woman of 34; under thyroid treatment the general condition improved, the periodicity and severity of the joint affection were materially modified and finally the attacks ceased entirely. Nearly two years have elapsed to date since the last attack. Before the thyroid treatment was commenced they had recurred every ten days for nearly two years, affecting both knees. The thyroid treatment was given at intervals from October, 1905, to March, 1908. The details of the case and of treatment are given in the *Bulletin de la Soc. Méd. des Hôp. de Paris,* 1910, xxvii, 96.

New and Nonofficial Remedies

SINCE THE PUBLICATION OF THE BOOK "NEW AND NONOFFICIAL REMEDIES, 1910," THE FOLLOWING ARTICLES HAVE BEEN ACCEPTED BY THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION. THEIR ACCEPTANCE HAS BEEN BASED LARGELY ON EVIDENCE SUPPLIED BY THE MANUFACTURER OR HIS AGENT AND IN PART ON INVESTIGATION MADE BY OR UNDER THE DIRECTION OF THE COUNCIL. CRITICISMS AND CORRECTIONS TO AID IN THE REVISION OF THE MATTER BEFORE PUBLICATION IN THE BOOK ARE ASKED FOR.

THE COUNCIL DESIRES PHYSICIANS TO UNDERSTAND THAT THE ACCEPTANCE OF AN ARTICLE DOES NOT NECESSARILY MEAN A RECOMMENDATION, BUT THAT SO FAR AS KNOWN IT COMPLIES WITH THE RULES ADOPTED BY THE COUNCIL.

W. A. PUCKNER, SECRETARY.

(Continued from page 1545)

CHINOSOL.—Normal Oxychinolin Sulphate.—Chinosol is a normal oxychinolin sulphate $(C_9H_7ON)_2H_2SO_4$.

Chinosol is a yellow crystalline powder of saffron-like odor and burning taste. It melts at from 175° to 177.5° C. (347° to 351.5° F.). It dissolves readily in water but with difficulty in alcohol and it is insoluble in ether. The aqueous solution has an acid reaction.

A drop of solution of ferric chloride produces in a solution of chinosol a marked green coloration. Barium chloride produces a white precipitate. Solutions of alkaline hydroxides precipitate from an aqueous solution of chinosol a white precipitate, consisting of interlaced crystalline needles, which after filtration, washing and careful drying in a desiccator should melt at from 73° to 75° C. On incineration chinosol should not leave a weighable residue.

Actions and Uses.—So far as experimental evidence goes, chinosol is nontoxic. It is a powerful antiseptic equal in this respect to mercuric chloride and considerably stronger than phenol. It exerts an antiseptic action in solutions containing 1 part to 5,000. It is a feeble germicide being weaker than phenol and much weaker than mercuric chloride.

Dosage.—For internal use 0.3 Gm. (5 grains) three times daily. As an antiseptic the average strength of solution is 1 to 1,000; as a nasal or vaginal douche, it is best given with 1 part to 5,000, and as an eye-wash 1 to 8,000, gradually increasing the strength of the solution according to the sensitiveness of the patient.

Manufactured by Franz Fritzsche & Co., Hamburg, Germany (Chinosol Co., Parmele Pharmacal Co., New York). U. S. patent No. 906,918. U. S. trademark No. 28,750.

DIGIPURATUM.—Digipuratum is a purified extract of digitalis, said to contain about 0.4 per cent. of digitoxin and 4 per cent. of digitalin in the form of a tannate. It is standardized biologically by the method of Gottlieb. It is claimed that 85 per cent. of the inactive substances found in the ordinary extract have been removed and that it is free from digitonin and other gastric irritants.

Digipuratum is a greenish yellow, odorless powder of bitter taste. The active constituents of digipuratum are insoluble in cold water and diluted acids, but are easily soluble in weak alkalies.

Digipuratum responds to the following identity test: If 0.1 Gm. digipuratum is underlaid with about 3. Cc. of glacial acetic acid which contains 1 per cent. of a 5 per cent. solution of ferric sulphate, there appears a red band (presence of digitalin) and above this another, at first bright green, later changing to dark green and finally blue (presence of digitoxin).

To determine the digitoxin content, 10 Gm. of digipuratum are dissolved with moderate heat in 50 Cc. of water; 5 Cc. of 10 per cent. ammonia water are added and the liquid is then extracted with chloroform. The chloroformic extractions are filtered into a tared vessel and the chloroform removed by distillation. The residue is dissolved in 3 Gm. of chloroform and mixed with 7 Gm. of ether and 50 Gm. of petroleum ether. The separated flakes are collected on a small filter. Then the residue on the filter is dissolved in absolute alcohol, allowing the solution to run into the tared distilling vessel. The alcohol is then distillated off and the residue dried to constant weight. The digitoxin thus found should not amount to more than 0.04 Gm.

The physiologic activity is determined by the method of Gottlieb: 1 Gm. of digipuratum is dissolved with heating in 19 Cc. of water and 1 Cc. of a 2 per cent. solution of sodium bicarbonate. If now 0.15 Cc., 0.2 Cc., and 0.25 Cc., respectively, of this solution is injected into the femoral lymphatics of freshly caught land frogs (rana temporaria), weighing 30 Gm. each, the exposed heart of the animals should permanently be brought to a stop in the majority of instances (say in five out of six experiments) within half an hour after the administration of a 0.2 Cc. dose. If 0.2 Cc. of the 5 per cent. solution=0.01 Gm. of digipuratum, is sufficient to stop the systolic heart-beat within half an hour, then 1 Gm. of digipuratum will contain 100 units; should 0.25 Cc. of the 5 per cent. solution be necessary, the number of units of digipuratum it contains would be 80; if 0.25 Cc. should not yet prove sufficient, the preparation would be too weak to be effective; and should the systole be arrested after a dose of 0.15 Cc. within half an hour after injection, the preparation would be too strong.

The total physiologic activity having been determined, the relative amount that is due to digitoxin can be determined by using the digitoxin separated in the above quantitative determination and by the difference between this amount and the total physiologic activity the amount due to the digitalin alone can be estimated.

Actions and Uses.—The same as digitalis, but it is claimed that it is less liable to disturb the stomach and on account of its exact dosage cumulative effects can be more easily avoided than with other preparations of digitalis.

Dosage.—The same as digitalis.

Manufactured by Knoll & Co., Ludwigshafen a. Rh. and New York. U. S. patent No. 943,578. U. S. trademark No. 73,012.

Digipuratum Tablets, 1 1-2 grains.—Each tablet is said to contain digipuratum 0.1 Gm. (1 1/2 grains).

SECACORNIN.—Ergotin Roche.—Secacornin is a solution of the active principles of ergot in a menstruum consisting of distilled water, glycerin and 7.5 per cent. of alcohol. 1 Cc. of secacornin corresponds to 4 Gm. of ergot U. S. P. and is said to be standardized according to the method of Kehrer (Arch. f. exp. path. u. Pharm., vol. lviii).

Secacornin is prepared from ergot by removing fat by means of benzin or similar solvent and exhausting by percolation with diluted alcohol. The total percolate is then deprived of its alcohol by distillation in vacuo. The resinous mass which separates after cooling is then carefully drained off and the clear filtrate having been evaporated to the consistency of an extract is mixed with the general vehicle.

Secacornin is a dark brown solution, said to be sterile. It is claimed that it does not deteriorate on keeping.

Secacornin responds to the following identity test: 1.6 Cc. secacornin is mixed with 3.0 Cc. distilled water, and 5 drops of 10 per cent. ammonia water, and shaken out in a separatory funnel with 20.0 Cc. of ether. After complete separation of the two liquids, the aqueous solution is allowed to flow off, the remaining ether washed with 2.0 Cc. distilled water, and the wash-water likewise carefully separated. After this the ethereal solution is filtered into an Erlenmeyer flask, and traces of water removed by the use of as much anhydrous sodium sulphate as can be held on the point of a knife. Following this it is filtered into a small glass dish and cautiously evaporated.

The residue is then dissolved in from 1 to 1½ Cc. ferric chloride-acetic acid (1 drop of Liq. ferri chloridi with 200 Cc. acetic acid). To this solution is added with a pipette, cautiously and without mixing, in order to form an understratum, 3.0 Cc. pure concentrated sulphuric acid. At the point of contact of the two liquids a characteristic blue to violet ring forms after a time.

Action and Uses.—The same as ergot.

Dosage.—0.5 Cc. (8 minims) are equivalent to 2 Cc. (30 minims) of fluid extract of ergot U. S. P. It may be given by intramuscular injection in doses of 0.5 to 1 Cc. (8 to 15 minims).

Manufactured by F. Hoffmann-LaRoche & Co., Basel, Switzerland (The Hoffmann-LaRoche Chemical Works, New York). Not patented. U. S. trademark No. 58,830.

DESICCATED THYMUS—Armour.—Desiccated Thymus—Armour, consists of the fresh thymus gland of the calf freed from fat, cleaned, dried and powdered, without the addition of preservative or diluent.

A very light yellow powder, having a peculiar odor. Partly soluble in water.

One part represents approximately 5 parts of the fresh thymus gland. It is rich in nucleoprotein and in lymphoid tissue. Upon incineration, it should yield not more than 12 per cent. ash.

Actions and Uses.—See Thymus Gland (N. N. R., 1910, 144).

Dosage.—0.13 to 0.25 Gm. (2 to 4 grains) three times daily.

Manufactured by Armour & Co., Chicago. Not patented or trademarked.

Thymus Tablets-Armour.—Each tablet contains desiccated thymus 0.065 Gm. (1 grain).

Dose.—2 to 4 tablets three times a day.

THE MEIOSTAGMIN REACTION

Immunity reactions are constantly gaining a wider field of usefulness as diagnostic aids, and as new facts are discovered, exact diagnosis will doubtless be a matter of comparative simplicity in a great number of diseases in which one has to rely now on more or less equivocal signs, at least in the atypical or mild forms of disease.

Recently, Ascoli[1] has discovered a new phase of immunity reactions, which is physiochemical in nature and consists in a determination of the surface tension of an immune serum plus its specific antigen before and after incubation at 37 C. for two hours. He employs the stalagmometer of J. Traube for measuring the surface tension; by means of it, one can determine exactly the number of drops in a given quantity of fluid. Since after incubation he finds a lowering of the surface tension and a consequent decrease in the size of the drops (as will be shown later), Ascoli designates the test the "meiostagmin" reaction, from Greek words meaning "small" and "drop."

The first disease investigated was typhoid fever. From patients suffering with the disease, serums were obtained which agglutinated typhoid bacilli in dilutions ranging from a strength of 1 to 80 to that of 1 to 360. For the antigen, an alcoholic extract of typhoid bacilli was prepared, according to the method of M. Neisser and Shiga.[2] The serum was employed in a dilution of 1 to 10, the antigen in dilutions of 1 to 1,000, 1 to 10,000, 1 to 100,000 and 1 to 1,000,000; 0.85 per cent. sodium chlorid solution was always used as the diluent. To 9 c.c. of the diluted serum 1 c.c. of diluted antigen was added, and the number of drops in the mixture was immediately determined. The fluid was incubated for two hours and, after being allowed to cool to room temperature, the number of drops was again determined. When antigen, in dilutions ranging from a strength of 1 to 1,000 to that of 1 to 100,000, was used, a lowering of the surface tension was always found, as shown by the increase in the number of drops by two to three. This constituted a positive reaction. Ascoli found that normal serums, used as controls, when united with typhoid antigen and incubated, showed no decrease in the size of the drops. Similarly, negative result was obtained with typhoid serums when an alcoholic extract of colon bacilli was substituted for the typhoid antigen.

Izar,[3] a pupil of Ascoli, extended the study of the meiostagmin reaction to twelve luetic serums with very interesting results. The antigen was prepared from the spleen of a syphilitic fetus. The serum was diluted with physiologic salt solution, the proportions varying from 1 to 20 to 1 to 100, the antigen being diluted 1 to 100 in all experiments. The two were united in the proportions employed by Ascoli with typhoid. Of the luetic serums tested, eleven gave a positive Wassermann reaction, while with the meiostagmin reaction all were positive, the increase in the number of drops varying between two and five.

For control, other antigens were prepared from material showing tuberculosis, carcinoma, sarcoma, echinococcus and typhoid. All were negative with the luetic serums; the number of drops was never increased more than one. As a further control, serums from patients suffering from a number of diseases other than syphilis were tested with syphilitic antigen. The most interesting of these were two serums obtained from leprous individuals, both of which gave a positive Wassermann reaction. They were sent to Izar with the statement that they yielded a positive Wassermann reaction, and it was only after a negative meiostagmin reaction was obtained that he learned that the patients were leprous and not luetic. The positive reactions, then, included the twelve patients known to be luetic, all controls being negative.

Finally, Ascoli and Izar[4] have sought to apply the meiostagmin reaction to the diagnosis of malignant neoplasms. Preliminary to their observations on human material, they examined the serums of normal and sarcomatous rats; positive reactions were obtained in all of nine sarcomatous animals, while eight normal controls were negative. After obtaining these results, human serums were tested against sarcomatous rat antigen and, in the later cases, against carcinomatous human antigen. (Ascoli and Izar give the preparation of the antigen in detail.) Their material included sixty-two patients suffering with malignant tumors, both carcinomas and sarcomas, a majority of the diagnoses being confirmed by histologic examination of tissue. Of these patients, fifty-eight gave a positive meiostagmin reaction; forty-eight patients suffering with other diseases (including two with lipomas and two with leukemia) all reacted negatively.

Ascoli and Izar are cautious in their conclusions. The results thus far obtained make it appear that the meiostagmin reaction is specific and that its field of application may be extensive. The great simplicity of the technic as compared with that of the Wassermann reaction should bring the method into almost immediate general use. if the results prove to be dependable. It remains, however, for further observations to demonstrate to what extent the reaction may be relied on as an aid to diagnosis.

THE CHINOSOL REPORT

The report by the Council on Pharmacy and Chemistry, which appears elsewhere[1] in this issue, is of more than ordinary interest. The preparation with which the report deals—Chinosol—was originally advertised as a most remarkable antiseptic and germicide free from the dangers of poisoning. These claims were so important that an investigation of the product was undertaken by the Council, the results of which were published as a report in THE JOURNAL Jan. 25, 1908. This investigation verified the statement that Chinosol is a good antiseptic, but it showed, on the other hand, that the germicidal action of the product is vastly inferior to that which was claimed for it. In its report, the Council accepted the conclusions of Weyl—since proven erroneous—that Chinosol has toxic properties and it pointed out that the chemical composition, as given by the American agents, had repeatedly been shown to be false and could be so demonstrated by a very simple analysis.

The American agents, the Parmele Pharmacal Co., having challenged not only the conclusions of the report but also some of the facts, the Council ordered a complete reinvestigation of the disputed points, by an independent bacteriologist, as well as by its original referee. This has extended over two years, and in the meantime additional confirmatory evidence has been obtained by eminent and independent investigators in England and Germany. The conclusions which the Council has drawn from its second investigation are presented in the present report. In brief, it is shown that the work of the original referee and the conclusions based directly on this work, were correct in every particular, but that the Council made a mistake in accepting Weyl's conclusions as to the toxicity of the product.

Regarding the false statements in the advertisements dealing with the composition of the product, the agents have since explained that they quoted *verbatim* from the United States Dispensatory, and that they did not know that any controversy had arisen as to the chemical composition. As to the matter of toxicity, the headline in the Council's original report, "Not free from danger of poisoning," went beyond the evidence. The Council had not itself investigated this point and was misled by a definite quotation. The experiments which the Council has since conducted have failed to bring out any evidence that Chinosol is harmful. While this, being negative evidence, is not conclusive proof that the product is absolutely harmless it must be conceded that so far as our present knowledge goes, there is no ground for challenging the claim of safety. Public safety and professional responsibility require that claims of absolute freedom from danger shall be supported by incontrovertible and unassailable evidence. The Council takes the attitude that in such cases a large number of negative observations are practically invalidated by a single, well-authenticated positive observation—an attitude which is unimpeachable in principle.

The most important findings of the Council, however, relate to the antiseptic and germicidal action of the preparation. Regarding the antiseptic value there has been no dispute. As to the other point, however, the Council confirmed its first report, that Chinosol is practically valueless as a germicide. This conclusion—and it was really the main issue of the first report—has been abundantly confirmed by independent investigators both at home and abroad, and in regard to it there can be no doubt. The experimental results on which the agents for Chinosol based claims, having been shown conclusively to be vitiated and invalidated by the want of proper experimental precautions. In extenuation, however, it should be said that the company was led into its serious error by a mistake of its technical advisers, a mistake which could be discovered only by experts.

The distinction between germicide or disinfectant and antiseptic or preservative is sometimes lost sight of and yet the difference is a vital one. A substance that is excellent for inhibiting the growth of bacteria (antiseptic) might be valueless as a killer of bacteria (germicide). It is evident, therefore, that to rely on the claims that were previously made for germicidal power would be extremely dangerous, and might more than offset any good that might follow the legitimate use of the article in its proper field as an antiseptic. The physician and surgeon must know exactly the limitations of such a remedy in both directions.

The report illustrates once again the need of independent and critical investigation of all proprietary remedies. It is necessary, not only to prevent fraud, but also to discover false claims made in perfect good faith and on apparently good authority. These last are, in some ways, the most dangerous: A manufacturer who was sincere in his false convictions would be likely to employ his superior material resources in such a way that an isolated independent investigator would scarcely obtain a hearing. It is doubtful whether such claims could be challenged successfully, except by an independent but official organization, possessed of the resources of the Council. The incident also illustrates the pains which the Council takes to get at the truth of disputed points. It shows too, that a manufacturer who has any legitimate grievance against the Council, may be assured that his representations will be considered fairly and without prejudice.

A NEW COMBINATION AGAINST THE AMERICAN MEDICAL ASSOCIATION

Within the past few days the newspapers of the chief cities of the country have carried large advertisements headed: "Do You Want the 'Doctors' Trust' to be able to Force its Opinions on You?" These advertisements paint in vivid colors—"yellow" predominating—the disaster and general destruction that will follow the formation of a federal department of health. They emanate from, or to be more correct, are signed by, an organization calling itself the "National League for

---

"Medical Freedom." In addition to the regular display advertisements, the press agent is supplying matter for the reading pages, and there is every evidence that the propaganda is not lacking financial support. Of course the American Medical Association is the *bête noir* the "league" seeks to kill; it is the "medical trust" referred to. Members of the Association will be surprised to learn that if a national department of health is created it will result in "denying to the people the right to determine for themselves the kind of medical treatment they shall employ." For this reason, and so far as the advertisements *state*, for *this* reason only, the National League for Medical Freedom has been brought into being. As a slogan under which the real reasons for organizing may be carefully concealed, it may serve its purpose. Most people prefer to have their thinking done for them and this alone will prevent the absurdity of such a proposition, as that on which the "league" is ostensibly founded, becoming apparent. Yet every person with the most elemental knowledge of our government knows that the regulation of the practice of medicine and the licensing of physicians is a function of the state and that any law attempting to confer such power on a department of the federal government would be unconstitutional. The proposed department of health would have just as much authority to determine what "kind of medical treatment" the people should employ as the Department of Agriculture has to dictate to the farmer regarding the implement company he shall buy his plows of. Yet, we are asked to believe, apparently, that a national department of health would mean that the free-born American citizen who wanted to have a purulent appendix cured by the "spinal adjustment" route, would have to patronize a surgeon, even though he were a "conscientious objector" to surgery. It would mean, it seems, that the individual suffering from malaria who wished to be freed from this "moral error" by "absent treatment" would be ignominiously dragged to the internist and dosed with quinin. It would mean that the optimist who would cure his rheumatism by wearing a "guaranteed magnetic ring," would have to endure the administration of the salicylates. It would mean—but why pursue these harrowing predictions further?

Seriously, though, there must be something wrong with the mental make-up of the individuals composing this "league" who expect—even by such potent means as the lavish distribution of printers' ink—to persuade a reasonably sane people that any law might, could or would be enacted that would curtail the rights of the public as they have suggested. Of course, the fact is that the moving spirits behind the organization of the "league" have neither an overwhelming solicitude for the public welfare nor any strenuous objection to the formation of a national department of health. The "league's" actual, and fairly evident, *raison d'être* is opposition to and antagonism against the American Medical Association. To disclose the source of this opposition it is only necessary to call attention to some of the members of the "advisory board"—high-sounding title—as reported in the newspapers, to make reasonably clear to the members of the American Medical Association the "power behind" the "league." The publisher of the *Medical Standard* and *Western Druggist*, for instance, has long been known as a defender of, and mouthpiece for the "patent medicine" and proprietary interests. His presence on the "advisory board" is fitting, and the only surprising thing about it is that he should have been guilty of such a tactical blunder as getting into the fierce light of publicity.

That the president of the A. D. S. should be on the "board" was to be looked for, and being looked for, is found. And there are others! Among the lesser satellites in this distinguished galaxy are those who very naturally might be expected to enter enthusiastically into such a campaign—the president of an antivivisection society, some "mental healers" and one or two journalists of varying degrees of obscurity. Of the latter, one has for years been strongly opposed to medical organization and more recently has taken up that mental vagary known as "new thought." Taking into consideration both the objects of the "league" and the personnel of its "board" one feels that the New York *Journal* expressed only a half-truth when it said:

> "The druggists and the proprietary medicine interests throughout the country are said to be chiefly concerned in defeating the Owen bill."

It would have been nearer the facts if for "defeating the Owen bill" were substituted the clause "attempting to disrupt the American Medical Association." A dozen years ago the public might not have been able to see the animus prompting this attack—today it is wiser.

As to the publicity which this sensational and costly campaign will give to the American Medical Association the medical profession may welcome it. One thing that has long been needed is that of directing the attention of the laity to the aims and accomplishments of the American Medical Association. It welcomes investigation—the more the public learns about the work the Association is doing the better for the Association. It has nothing to be ashamed of, but it has a great deal to be proud of; its work in the interests of both public welfare and scientific medicine is and always has been open and above board. The Association needs no defense; it is not only well able to stand on its record, but is proud of that record.

EFFECTIVE PRACTICAL WORK AGAINST TUBERCULOSIS

Some splendid examples of work that should prove highly effective in the campaign against tuberculosis and the spitting habit are reported from Salem,[1] Mass., and Rochester, N. Y. The carefully laid plans of the

---

[1] The Salem campaign was described in The Journal, April 23, 1910, p. 1398.

Rochester Public Health Association included a billboard and advertising-sign campaign against the spitting evil, the distribution of small printed slips bearing warning against promiscuous spitting, factory talks of ten minutes each at noon by physicians, night meetings, a Children's Day, when the school children were instructed by prominent physicians on how to avoid disease, talks to fraternal organizations, trades unions, etc. One of the most valuable features was a series of "Tuberculosis Talkettes" in the five daily newspapers of Rochester by prominent physicians of the city, each "talkette" being a brief, terse presentation of a different phase of the tuberculosis question and the spitting evil. These consisted of not over forty or fifty lines in the paper, going directly to the point and telling in language easily understood by the layman the nature of tuberculosis, its cause, methods of transmission or contagion, the relation of the spitting habit to the spread of the disease, the necessity for personal and public hygiene, good habits, food, clothing, air, and various related subjects. All the subjects were treated in a way to show their practical application to the daily life and the welfare of each individual. The campaign reached its climax in a public meeting on April 22, at which Dr. Livingstone Farrand, executive secretary of the National Association for the Study and Prevention of Tuberculosis, Dr. John H. Lowman, Cleveland, O., and Professor Adolphus S. Knopf, New York, all enthusiasts in the fight against tuberculosis, gave addresses on tuberculosis. Following this meeting came Tuberculosis Sunday, observed all over the country, April 24, when the ministers of Rochester addressed their congregations on the work that had been done and the importance of its continuance. A long list of persons from the factories, mercantile establishments, fraternal orders, clubs, etc., was appointed by the Public Health Commission to act as permanent representatives in promoting the work of the Association. Such a vigorous campaign could scarcely fail to reach in some way every man, woman and child in the community, and its value in accomplishing the objects sought cannot be overestimated. Rochester and Salem are to be congratulated on these systematic efforts, which should serve as models everywhere, and then much real progress in the war on tuberculosis would be made.

IS IT TRUE? ASK YOUR DRUGGIST!

Elsewhere we call attention to the source and character of the opposition that has developed, ostensibly against the bill providing for a national department of health but actually against the American Medical Association. It is said that in the hearing before the committee having the bill in charge, Senator Smoot read a letter from the president of the National Association of Retail Druggists (and of the American Druggists Syndicate), claiming that 40,000 members of the N. A. R. D. were against the bill! If this statement is true it is well that the physicians of the country should know it; if it is false then the president of the N. A. R. D. (and of the A. D. S.) has grossly libeled and misrepresented the retail druggists of the country. We believe the statement, if made as reported, to be unequivocally false. We believe that the vast majority of the druggists who are members of the N. A. R. D. are in hearty sympathy with the aims and efforts of the medical profession to conserve the public health. We believe that while some of the officers of the N. A. R. D., because of their connection with the A. D. S., are bitterly opposed to the American Medical Association and all it stands for, they do not in any sense represent the attitude of the members of the former organization. In fact, it is unthinkable that the decent pharmacists of the United States should be lined up with "patent medicine" fakers, "newthought" faddists, antivivisection cranks, *et hoc genus omne.*

ORANGE-RED CLOTHING NO IMPROVEMENT

The acquisition by the United States of its island possessions and of interests in Panama and Cuba has raised many new problems concerning the health and comfort of the forces of occupation and administration in tropical climates. Among the questions arising has been the one of suitable clothing. An experiment made in the Philippines among the military forces was the use of orange-red underclothing as a protection against heat, and especially as a preventive of heat exhaustion. This experiment was made following the report of the British officers in India that such clothing was much more comfortable than the white in hot weather. The test clothing was distributed to half the men in each company, the other half wearing white garments of like texture as a control. In all 500 men wore the orange-red underwear, under similar conditions of physique, food and service, and careful records were kept of comparative amounts and nature of sickness among them, their feelings as to comfort or discomfort in the sun, their mental and bodily vigor, etc. The experiments continued for a year and a record of the weights and blood examinations were kept throughout this period. It was found that the record of sick admissions was about the same for both groups, they suffered equally from the heat of the sun, but those of the orange-red group suffered more from excessive perspiration, there was a greater loss of weight in the hot season by nearly a pound per man, and the blood changes noted in tropical climates—increase of red cells and loss of hemoglobin—were more pronounced. The blood pressure also showed a greater loss and the temperature, pulse and respiration showed a slightly higher rate for this group. The admissions for heat exhaustion and febricula were not reduced by the orange-red underclothing and the symptoms due to heat were about the same in the two groups. Only sixteen men out of the five hundred preferred the colored underclothing, and the persistent complaints of greater heat, greater weight and excessive perspiration indicated that the colored garments are more receptive to the heat rays than the white. The conclusion of the board conducting the experiment was that the orange-red clothing added materially to the burden of heat on the system; that while it protected from the chemical ray, the influence of this ray is negligible and it is sufficiently excluded by khaki clothing and the campaign hat, and that no beneficial effect was observed from this clothing.

Medical News

CALIFORNIA

Violates Medical Law.—Chow Juyan, a Chinaman, was fined $100 by Police Judge Deasy, San Francisco, May 5, with the alternative of fifty days' imprisonment in jail for practicing medicine without a license.

Children's Clinic Opened.—A free clinic has been opened by the Pasadena Hospital for children of the Pasadena schools. The clinic, while free to those who cannot pay, will be supported in part by contributions.

Fraternity Election.—At the annual election of the Delta Chapter of the Phi Rho Sigma Fraternity, College of Medicine of the University of Southern California, Los Angeles, held April 29, the following officers were elected: President, Dr. Milbank Johnson, Los Angeles; vice-presidents, Drs. Andrew S. Lobingier, Los Angeles, and Rexwald Brown, Santa Barbara, and secretary-treasurer, Dr. W. R. Maloney.

ILLINOIS

Fined for Violating Medical Practice Act.—Mrs. Ernestine Petersen, matron of the so-called Red Cross Sanitarium, Rock Island, on May 4, is said to have been fined $100 and costs on each of ten charges of violating the medical practice act of Illinois.

Personal.—Dr. William W. Williams has been elected president and Dr. Kirk S. Shawgo, secretary of the staff of the Blessing hospital, Quincy.——Dr. Edward Bowe has severed his connection with the Maplewood Sanatorium, Jacksonville.——Dr. Orlando F. Scott has been appointed health officer of Summit and Argo.

Court Doings.—In the case of Dr. St. Elmo M. Sala, Rock Island, against Charles E. Dempsey, a verdict was returned for the plaintiff May 17, with damages of $112. This case is interesting as the defendant had previously brought suit for $10,000 for malpractice and was non-suited. The litigation has continued for about five years.——In the case of Dr. Paschall N. Bowman, Gillespie, charged with manslaughter by the alleged unskilful performance of an operation, the jury was unable to agree and was discharged.

Society Meetings.—At the annual meeting of Brainerd District Medical Society, held in Lincoln April 28, the following officers were elected: President, Dr. Harry G. Hardt, Lincoln; vice-presidents, Drs. Charles W. Carter, Clinton; Chauncey W. Cargill, Mason City, and Edwin P. Sloan, Bloomington; secretary, Dr. Harry S. Oyler, Lincoln; treasurer, Dr. Chas. C. Reed, Lincoln, and censors, Drs. Irving Newcomer, Petersburg; James H. Butler, Hartsburg, and Albert E. Campbell, Clinton. The next meeting will be held in Springfield in July.——The thirty-sixth annual meeting of the Central Illinois District Medical Society was held in Pana April 26. The following officers were elected: President, Dr. Roscoe C. Danford, Pana; vice-presidents, Drs. George J. Rivard, Assumption, and William H. Sparling, Moweaqua; secretary, Dr. Walter Burgess, Pana, and treasurer, Dr. John N. Nelms, Taylorville; censors, Drs. Jacob Huber, Louis H. Miller, and Frederick J. Eberspacher, Pana; Dr. William J. Eddy, Shelbyville, and Dr. Dorwin D. Barr, Taylorville.

Chicago

Fined for Misbranding.—Mrs. Gervaise Graham is reported to have been fined twenty-five dollars by Judge Landis, May 16, for misbranding a dandruff cure. The wrapper bore a printed statement that a cure was guaranteed but the government declared that it is not possible to guarantee a cure for this condition of the scalp.

Byron Robinson Memorial Services.—Memorial services in honor of the memory of the late Dr. Byron Robinson were held at Whitney Opera House, May 22. President Charles R. Van Hise of the University of Wisconsin presided and Dr. William A. Evans gave an address on the life and work of Dr. Robinson.

Personal.—Dr. and Mrs. David Fiske and Dr. C. Bruce Walls and family have started for Europe.——Dr. Nils Theodore Quales has been awarded, by King Haakon of Norway, the order of St. Olaf.——Dr. Magnus-Levy, Berlin, who is staying in Chicago for a few days on his way West, was tendered a dinner at the University Club, May 23, by a few of his medical friends.

IOWA

Fined for Illegal Practice.—George Corwin, Brooklyn, a so-called chiropractic, charged with the illegal practice of medicine, is said to have been found guilty, April 1, and fined $300 and costs.

Hospital News.—The new addition to Graham Hospital, Keokuk, which will cost $15,000, will be completed and ready to receive patients July 1.——Waterloo is to have a new hospital in charge of the Franciscan Sisters. The building will be under construction this summer and will be ready for occupancy in July next year. The institution will be four stories in height, of fire-proof construction, and will accommodate 98 patients.

KANSAS

Hospital for Wellington.—The Commercial Club and soliciting committee for a hospital for Wellington obtained subscriptions of $10,000 in seven days. Of this, physicians of Sumner county subscribed $3,000. The hospital is to be in care of Bishop Frank Milspaugh.

Fine Increased After Appeal.—James Black, a negro who was recently fined $200 and given a sentence of sixty days in jail by the police judge in Kansas City for selling cocain, and appealed his case to the district court, had a rehearing, May 2, and was fined $300 and given a sentence of ninety days' imprisonment in jail.

KENTUCKY

School Children's Teeth Examined.—By authority of the health department and health officer of Louisville, the teeth of every school child of the city is to be examined. The actual work will be done by members of the Jefferson County Dental Association.

Decided Against Physician.—The suit of Miss Laura Crews, Lexington, against Dr. Benjamin F. Van Meter, is said to have been decided in favor of the plaintiff, with damages of $4,000. The suit was for $25,000 and alleged the unskilful performance of a surgical operation without the consent of the patient. On hearing of the verdict the Fayette County Medical Society at once adopted a resolution of confidence in Dr. Van Meter.

Society Meetings.—Warren County Medical Society, at its meeting in Bowling Green, adopted resolutions extending a vote of thanks to the representatives and senator for their assistance in passing the Health Bill through the last legislature, and approving the Owen Bill.——Bullitt County Medical Society held its annual meeting in Shepherdsville April 11, and elected Dr. Walter W. Hill, South Park, president; Dr. Samuel W. Bates, Shepherdsville, vice-president, and Dr. A. Capiston Overall, Mount Washington, secretary-treasurer.——Muhlenberg County Medical Society, at its annual meeting in Central City, April 28, elected the following officers: President, Dr. John P. Walton, Central City; vice-president, Dr. Henry Y. Slaton, Greenville; delegate to the state medical society, Dr. Milton P. Creel, Central City, and alternate, Dr. Thomas G. Turner, Dunmor.——Muldraugh County Medical Society, at its annual session, April 14, adopted resolutions favoring the creation of a national department of health.

LOUISIANA

Auto Ambulance.—A new automobile ambulance, donated to the Charity Hospital, New Orleans, by the members of Mecca Temple Ancient Order of the Nobles of the Mystic Shrine, New York City, at a cost of $9,000, was received from New York, April 11, and was at once put into commission.

Personal.—Dr. Charles J. Landfried has been appointed surgeon in charge in the ear, nose and throat department of the Eye, Ear, Nose and Throat Hospital, New Orleans, to succeed Dr. Oscar Dowling, Shreveport, who was recently elected but resigned.——Dr. C. Milo Brady, New Orleans, has returned after several months spent in the study of tropical diseases on the West Coast of Africa.——Dr. and Mrs. Louis A. Meraux, New Orleans, left for Europe May 14.

Society Meeting.—At the annual meeting of East Feliciana Parish Medical Society, held at the Insane Hospital of the State of Louisiana, Jackson, April 6, the following officers were elected: President, Dr. Jesse W. Lee, Jackson; vice-president, Dr. William F. H. Hagaman, Norwood; and secretary-treasurer, Dr. Robert P. Jones, Clinton. By unanimous vote, the society dropped from its rolls Dr. Emmett C. McKowen, Clinton, who is said recently to have been found guilty of murder in connection with the death of a patient in the insane hospital.——Claiborne Parish Medical Society, at its annual meeting in Athens, April 27, reelected the following officers: President, Dr. Joseph W. Day, Homer; vice-presidents, Drs.

Phillip Gibson, Homer, Lee T. Waller, Haynesville, and James F. Simpson, Athens; secretary-treasurer, Dr. William L. Stone, Homer, and delegate to the state society, Dr. Lee T. Waller.

MAINE

Off for Europe.—Drs. Oliver W. Turner, Albert H. Sturtevant, Wellington Johnson, William H. Harris and George R. Campbell, Augusta, Dr. Lewis K. Austin, Waterville, and *Dr. and Mrs. John G. Gehring, Bethel, have started for Europe.*

Hospital Staff Elected.—The trustees of the Webber Hospital, Biddeford, have elected the following staff: Surgery—Drs. M. Hubbard Ferguson and Caleb J. Emery, Biddeford, and Jasper D. Cochrane and Clarence E. Thompson, Saco; medicine—Drs. Augustus Thayer, Addison S. Thayer and Charles B. Witherle, Portland, and Dr. Samuel J. Bassford; eye and ear—Drs. John W. Bowers, Dexter J. Clough, Erastus E. Holt, Willis B. Moulton, Albion H. Little and William Moran, Portland, and Dr. Charles M. Sleeper. South Berwick; nose and throat—Drs. John H. Allen and Owen P. Smith, Portland; and obstetrician—Dr. Stanley P. Warren, Portland. The consulting staff includes Drs. F. S. Warren, Biddeford, James O. McCorrison, North Berwick, John L. M. Willis, Eliot, Frank M. Ross. Kennebunk, Harry L. Prescott, Kennebunkport, Joseph W. Gordon, Ogonquit, Jesse A. Randall, Old Orchard, Charles W. Blagden, Sanford, Fred A. Bragdon, Springvale, and Drs. Edville G. Abbott, William H. Bradford. Henry H. Brock, William L. Cousins, Fred H. Gerrish, Arthur S. Gilson, Seth C. Gordon. Alfred King, Charles M. Leighton, Alfred Mitchell, Jr., Willis B. Moulton, Richard D. Small, John F. Thompson, Philip P. Thompson, Walter E. Tobie and Herbert F. Twitchell, Portland.

MASSACHUSETTS

Carnation Day at Lynn.—May 14 was observed in Lynn as "carnation day" and 30,000 carnations were sold for the benefit of the State Tuberculosis Camp, Swampscott.

Personal.—Dr. Frank H. Zabriskie has resigned as a member of the board of health of Greenfield.——By the will of Mrs. Annie Preston Lincoln, Boston, Dr. Edward B. Kellogg is bequeathed $25,000.——Dr. Ralph B. Ober, Springfield, is reported convalescent from the effects of septicemia due to a postmortem wound.

Tuberculosis Camp Opened.—The camp of the Springfield Association for the Prevention of Tuberculosis was opened for the summer at East Longmeadow, May 12, with six patients in attendance. The present capacity of the camp is twenty-two.

MISSISSIPPI

Personal.—Dr. Thomas J. Mitchell, for many years superintendent of the State Insane Hospital, Asylum, has resigned and will practice in Jackson.——Dr. Waller S. Leathers has been appointed director of public health and sanitation of the state board of health and chief bacteriologist of the state laboratory to be established in Jackson.

Hospital Appropriation Bill Passed.—Among the principal appropriation bills passed by the legislature is one appropriating $50,000 for the erection and equipment of a Central State Charity Hospital at Jackson. The bill contains a provision that the city of Jackson and Hinds county shall contribute $25,000 toward the building and equipment fund.

MONTANA

Ricketts' Memorial Prize.—At the closing session of the Montana State Medical Association, a resolution was adopted providing for a memorial medal, in honor of Dr. Howard Taylor Ricketts, to be given to the member presenting the best paper before the society at its annual session.

NEBRASKA

Graduation Exercises.—The College of Medicine of the University of Nebraska held its annual commencement exercises May 19, and graduated a class of seventeen. Robert H. Walcott, dean of the college, presided, and the doctorate address was delivered by Dr. Woods Hutchinson, New York City.——At the annual commencement exercises of the John A. Creighton Medical College, Omaha, April 30, forty-four were graduated from the medical department. Dean A. Hugh Hipple presided over the program of the evening.

State Association Meeting.—The forty-second annual meeting of the Nebraska State Medical Association was held in Lincoln, May 10-12, under the presidency of Dr. P. Harold Salter, Norfolk. The following officers were elected: President, Dr. John P. Lord, Omaha; vice-presidents, Drs. Harry M. Hepperlein, Beatrice, and Charles A. Anderson, Stromsburg; councilors, Drs. Anders P. Ovargaard, Fremont, John C. Malster, Stromsburg, Fletcher A. Butler, Harvard, John P. Gilligan, O'Neill, and Henry B. Lemere, Omaha; delegates to the American Medical Association, Dr. P. Harold Salter, Norfolk, and alternate, Dr. William J. Birkhofer, Goethenburg. The House of Delegates instructed the secretary to telegraph Senator Owen commending his efforts to secure the establishment of a national department of health. The society adjourned to meet next year in Omaha.

NEW HAMPSHIRE

State Society Meeting.—The New Hampshire Medical Society held its one hundred and nineteenth annual session in Concord, May 12 and 13, under the presidency of Dr. Frank Blaisdell, Goffstown. The following officers were elected and installed: President, Dr. Alonzo S. Wallace, Nashua; vice-president, Dr. George W. McGregor, Littleton; secretary (for five years), Dr. Pearl T. Haskell, Concord; councilor for Hillsboro county, Dr. E. Blaylock Atherton, Nashua; trustees, Drs. John M. Gile, Hanover, and John W. Parsons, Portsmouth; medical examiner, Dr. Arthur C. Heffinger, Portsmouth; alternate, Dr. Abram W. Mitchell, Epping; delegate to the American Medical Association, Dr. Ferdinand A. Stillings, Concord; alternate, Dr. John Z. Shedd, North Conway; delegates to state societies, Drs. J. W. Bates, Rochester, to the Maine Medical Association, Dr. Charles A. Morse, Newmarket, to the Massachusetts Medical Society, Drs. Arthur F. Sumner and George C. Wilkins, Manchester, to the Vermont State Medical Society, Dr. William H. Leith, Lancaster, and Ira J. Prouty, Keene, to the Medical Society of the State of New York, and Drs. Edgar O. Crossman, Lisbon, and John M. Gile, Hanover, to the Rhode Island Medical Society; necrologist, Dr. Eli E. Graves, Boscowen, and anniversary chairman, Dr. Charles S. Little, Laconia.

NEW JERSEY

Personal.—Dr. Patrick A. Shannon, New Brunswick, returned from Europe May 8.——Dr. William S. MacLaren has been appointed medical instructor in the public schools of Princeton Borough and Dr. Arthur K. MacDonald in the public schools of Princeton and Lawrence townships.

Society Meetings.—The annual meeting of the Medical Society of Hunterdon County was held in Flemington, April 26, and the following officers were elected: President, Dr. George Henry, Flemington; vice-presidents, Drs. Isador Topkins, Califon, and Henry H. Miller, Lebanon; secretary, Dr. Obadiah H. Sproul, Flemington; treasurer, Dr. Isaac S. Cramer, Flemington; and censors, Drs. George L. Romine, Lambertville; George N. Best, Rosemont, and Leon T. Salmon, Lambertville.——At the annual meeting of Salem County Medical Society, held in Salem May 5, the following officers were elected: Dr. George W. Fitch, Daretown, president; Dr. Henry T. Johnson, Pedricktown, vice-president; Dr. Henry Chavanne, Salem, secretary-treasurer; Dr. John F. Smith, Salem, reporter, and Drs. Emerson P. McGeorge, Woodstown; William H. James, Pennsville, and Richard M. Davis, Salem, censors.——The Society for the Relief of Widows and Orphans of Medical Men of New Jersey held its twenty-eighth annual meeting May 11, in Newark, and elected the following officers: President, Dr. Charles J. Kipp, Newark; vice-president, Dr. Archibald Mercer, Newark; secretary, Dr. Charles D. Bennett, Newark; treasurer, Dr. George R. Kent, Newark; custodians of the permanent fund, Drs. Norton L. Wilson, Elizabeth, and Thomas W. Harvey, Orange; and trustees, Drs. James H. Rosenkrans, *Hoboken, and Charles F. Underwood, and Edward Staehlin,* Newark.

NEW YORK

No Tuberculosis Sanatorium at Liberty.—The State Commissioner of Health, after a careful consideration of the application of the Independent Order of Brith Abraham of the United States of America, for permission to establish a preventorium and camp for the treatment of tuberculosis in the town of Liberty, felt constrained to deny the same, and has so notified the petitioners.

Practice Training for Health Officers.—Opportunities for the practical training of health officers in the work of inspection, diagnosis, quarantine, disinfection, etc., actual work of the daily duties of the Quarantine Station, are offered to all the health officers of the state throughout the summer by the courtesy of Dr. Alvah H. Doty, Health Officer of the Port of New York. These facilities are available for six persons at a time.

Mail for the Insane.—Attorney General O'Malley has given an opinion which establishes the rights of idiots and lunatics in the state institutions to receive mail. He states that the officers of such an institution have no right to open mail addressed to inmates, but have the right and the authority to make rules and regulations, subject to the approval of the State Board of Charities, preventing the delivery of letters to such inmates, or to prevent letters being sent by them to outside persons, when, in their judgment, this might cause interference with the safe administration of the affairs of the institution.

Opposed to Metropolitan Life Company's Institution.—It has been announced that the residents of Somers, within whose limits the proposed site for the sanatorium for the treatment of employees of the Metropolitan Life Insurance Company having tuberculosis lies, will make a vigorous fight against the erection of the proposed institution in this locality. Edward Hatch, the chairman of the pollution committee of the Merchant's Association, states that he considers that the establishment of a sanatorium for the treatment of tuberculosis within the boundaries of the water shed that supplies the drinking water for New York City will endanger the lives of millions of people.

Bills Signed by Governor.—Governor Hughes has signed the following bills: A bill providing that the Mount Vernon Board of Health shall consist of the mayor and at least six other persons: the Green Bill, amending the liquor tax law by prohibiting liquor to be sold or even given away except on the written prescription of a physician, to any patient affected with tuberculosis in a camp, colony or hospital established by the state, county or municipal authorities, and a bill bringing the Mohansic State Hospital under the jurisdiction of the State Lunacy Commission and authorizing the commission to provide for the committment of patients from any part of New York to this institution.

Deciding the Milk Standard.—The Baumes bill, which provides that the standard of milk in the state shall be lowered by declaring only such milk adulterated as contains less than 11½ instead of less than 12 per cent. of milk solids, has been argued before Governor Hughes. Many milk producers defended this measure, but the health commissioner of New York City was opposed to the reduction of the standard as being against the public interest in New York City. He stated that lowering the standard to the degree mentioned would make it possible to water the milk supply of New York City to the extent of 75,000 quarts daily, which would mean a daily loss of $6,000 to the people of that city. The New York State Breeders' Association also sent a protest against a lowering of the standard.——A bill designed to permit the sale of skimmed milk cheese and skimmed milk powder in New York and Kings counties has been passed by the senate after considerable hesitation. This bill, if it becomes a law, will permit the manufacture of skimmed milk products in New York City. It is stated that Commissioner Pearson of the State Department of Agriculture has given the bill his approval.

New York City

Off for Europe.—Drs. Graeme M. Hammond, Daniel M. Stimson and Frank B. Cross have sailed for Europe.

New Laboratory.—Mr. Adolph Lewisohn has given $130,000 to Mount Sinai Hospital for the erection of a pathologic laboratory building.

Heavy Sentence for Cocain Seller.—Edward Lewis, a cocain seller who has been arrested four times and convicted twice, has been sentenced to two years in the penitentiary.

Fellowship Established.—Mount Sinai Hospital announces the establishment of a second fellowship in pathology, the income of which amounts to $500 per annum, to be known as the Eugene Meyer, Jr., fellowship.

Open Hospital at Coney Island.—The Coney Island Branch of the Kings County Hospital was opened on May 18. The building is thoroughly modern and will accommodate 100 patients. Dr. Charles Durning will be Superintendent.

Measles on Ocean Liner.—The Cunard steamer, *Carpathia*, from the Mediterranean, was detained at Quarantine, May 10, on account of the presence of measles which necessitated the transfer to Hoffman Island of 40 of the 325 children which were on board.

Resolutions Regarding Dr. Goelet.—At a meeting of the Tri-Professional Medical Socie of New York, May 17, resolutions were adopted setting forth the careful; accurate and kindly work, the personal magnetism, the warm friendship and the love for truth, of its late me er, Dr. Augustin H. Goelet.

New Building for Medical School Work.—Work has been commenced on the new hospital building for the New York Postgraduate Medical School. The building will be twelve stories in height and will cost $600,000. It will be provided with ample means for open-air treatment including a roof pavilion.

The New York Neurologic Institute.—This institution has just made public the report of its first year's work. During the year 220 cases of nervous disease were registered. The growth of the institution has fully demonstrated the necessity for a hospital and dispensary devoted to diseases of the mind and nervous system. When the hospital was opened it was thought that ample provision had been made for some time to come, but there is already need of more extensive accommodations.

Dulness and Bad Teeth.—Dr. Luther H. Gulick, director of the department of child hygiene of the Russell Sage Foundation, states that at least one-half of the school children have defective teeth and that children with defective teeth take half a year longer to complete the eight grades of the elementary course than children who have good teeth. Dr. Gulick has conducted studies on 40,000 school children in New York City during the past two years. He advises further instruction in the public schools regarding the teeth and their care.

New Buildings of Long Island College Hospital.—During the past ten years the old Long Island College Hospital has been removed piece by piece and replaced by new buildings. The last section of the old building is now being removed to make place for a new wing. The entire cost of the new building will be about $2,000,000. The section now under construction will contain about 200 beds for male patients and the new hydrotherapeutic and electrotherapeutic equipment. This hospital has its own incinerator for burning garbage and obtains its supply of water from its own wells.

Buffalo

Tuberculosis Camp Opened.—The tuberculosis day camp was opened for the reception of patients, May 25.

Alumni Meeting.—At the annual reunion of the Alumni Association of the University of Buffalo, May 24, Dr. J. Clarence Webster, Chicago, delivered the Harrington lecture and a dinner was tendered to Dr. Matthew D. Mann in recognition of his many years of faithful service as professor of obstetrics and gynecology.

Tuberculosis Work in Buffalo.—The first annual report of the Buffalo Association for the Relief and Control of Tuberculosis shows that the day camp was open 141 days. During this time 95 patients were admitted, of whom 38 were male and 57 females. The total number of treatment days was 5,545, and the average daily attendance 39.32. Of the cases treated 25 were incipient; 23, moderately advanced; 41, advanced; 2, surgical; and 4 patients came for observation. During the two years the dispensary has been open 1,140 cases have been examined, of which 339 were definite cases of tuberculosis; 89 were doubtful; in 29 there were tubercular lesions other than of the lungs, and 683 patients, or nearly 60 per cent. were non-tubercular.

NORTH DAKOTA

Hospital for Minot.—At a meeting recently held in Minot, $9,000 was pledged for a Benedictine Sisters Hospital to cost about $70,000.

Health League.—A public health league was organized at Minot, April 30. Dr. Gustave F. Ruediger, Grand Forks, director of the state public health laboratory, delivered an address, at the conclusion of which the league was organized, with Dr. Andrew Carr, Minot, as vice-president.

Society Meetings.—At the annual meeting of the Traill and Steele County Medical Society, held in Portland, Dr. William E. White, Mayville, was elected president; Dr. Annt G. Anderson, Hillsboro, vice-president; Dr. Daniel E. Rogers, Portland, secretary-treasurer, and Dr. Edward C. Haagensen, Hillsboro, delegate to the state society.——A medical association for Burleigh county has been organized at Bismarck.

OKLAHOMA

Law Cases.—The jury acquitted Dr. Thomas E. Shepherd, Tulsa, who was charged with manslaughter.——Dr. Leander A. Riely, Oklahoma City, was sued for $5,000 for alleged failure to locate a broken bone in the leg and the verdict is reported to have been for $750.

Public Health Officials Meet.—The meeting of the Oklahoma Public Health Association was held in Tulsa May 10-12. Dr. Herbert L. Wright, Hugo, was elected president; Dr. Charles L.

Reeder, Tulsa, vice-president, and Willis A. Logan, Lehigh, secretary-treasurer. Before the close of the meeting, Dr. John C. Mahr, Shawnee, state commissioner of health, was presented by the members of the association with a diamond ring in appreciation of his work in behalf of the health of the state.

PENNSYLVANIA

Philadelphia

Honor Retiring Professor.—Dr. James Tyson who has recently retired from the teaching staff of the medical school of the University of Pennsylvania, was presented with a silver loving-cup and a silver platter by his senior and junior students, May 13.

Cocain Dealer Pleads Guilty.—Abraham Hall, a colored man, is said to have pleaded guilty in Quarter Sessions Court, April 26, to the charge of the unlawful sale of cocain and to have been sentenced to imprisonment in the eastern penitentiary for not less than six months nor more than two years, and to a fine of $500.

Resolutions Regarding Dr. Ricketts.—At a meeting of the College of Physicians of Philadelphia, May 13, resolutions were adopted setting forth the heavy blow sustained by medical science and the public welfare in the death of Dr. Howard Taylor Ricketts, briefly noting the research work done by Dr. Ricketts regarding blastomycosis, immunity, Rocky Mountain spotted fever and typhus fever; bearing witness to his remarkable qualities of intellect and personal qualities, and closing with the statement, "Thus this man died, leaving his death for an example of noble courage and a memorial of virtue, not only to young men but unto all his nation."

Labor Union to Fight Tuberculosis.—The Central Labor Union held a meeting on May 18, for the discussion of plans to be adopted in its proposed fight against tuberculosis. The meeting was arranged by J. Byron Deacon, secretary of the Society for the Prevention of Tuberculosis. Dr. James Tyson presided and addresses were made by Rev. George C. Richmond, rector of St. John's Episcopal Church, and P. V. Danshay, of Albany, a member of New York State Immigration Commission, director of the labor department of the New York State Charity Aid. It is proposed to establish a big double camp for day and night uses, where patients may go regularly for fresh air, milk and eggs, and three meals with nurses and physicians in attendance. In the day camp the patients would live in the open, going home to sleep at night. It would be part of the duty of the nurses to go to the homes, giving instructions there for open air sleeping. A night camp would be established for those workingmen who had been cured or who had the disease arrested and were able to return to the city to work.

SOUTH DAKOTA

Hospital Organized.—The German Baptist Hospital for the Dakotas was organized in Emery recently, and Dr. Carl A. Homan was elected chief surgeon.

Sanatorium Site Selected.—The State Board of Correction and Charities have selected the Hand Ranch, four miles south of Custer, as the most desirable location for the new tuberculosis sanatorium, for the erection of which the last legislature made an appropriation of $10,000. The ranch consists of 160 acres, of which 70 are in cultivation.

Personal.—Dr. F. A. Van Buren, Edgemont, has been appointed local surgeon for the Burlington System.——Dr. G. Hayward Coburn, Deadwood, was given a farewell banquet by the Black Hills Medical Society on the occasion of his approaching departure for Chicago.——Dr. Francis A. Moore, Lesterville, has gone to New York City for a year of post-graduate work.

Railway Surgeons Convene.—Surgeons representing the Chicago, Milwaukee & St. Paul and Chicago & Northwestern railroads held their annual meeting in Rapid City, May 11, and elected the following officers: Dr. William E. Moore, Tyndall, president; Dr. Delorme W. Robinson, Pierre, vice-president; Dr. John L. Foxton, Huron, secretary-treasurer, and Drs. C. W. Hargens, Hot Springs, William R. Ball, Mitchell, and Hiram E. McNutt, Aberdeen, executive committee.

TENNESSEE

Personal.—Dr. William Hardy, a recent graduate of the Medical Department of Tennessee University, Nashville, has been ordained as a missionary, and will sail from San Francisco to his new field of work in Batang, Thibet, May 24.

New County Society.—The McNairy County Medical Society was organized at Selmer, April 21, and the following officers were elected: President, Dr. William H. Hodges, McNairy; vice-president, Dr. James L. Smith, Selmer; secretary, Dr. W. T. Bell, Selmer; and treasurer, Dr. J. R. Smith, Selmer.

State Association Election.—At the annual meeting of the Tennessee State Medical Association held in Memphis, May 12 to 15, Dr. John A. Witherspoon, Nashville, was elected president and Drs. Richard A. Barr, Nashville, Joseph J. Waller, Oliver Springs, and J. H. Eugene Rosamond, Memphis, were elected vice-presidents.

TEXAS

Medical Directors Meet.—The Texas Association of Medical Directors held its first annual session in Dallas May 10. Dr. John H. Florence, Houston, was elected president; Dr. John S. Lankford, San Antonio, vice-president, and Dr. Mathew M. Smith, Dallas, secretary-treasurer. The membership includes both medical directors of both old-line life and fraternal insurance companies.

Alumni Associations Organized.—At a meeting held in Dallas, May 11, Memphis Hospital Medical College Alumni Association for Texas was organized with the following officers: President, Dr. R. Walter Smith, Moffat; vice-president, Dr Samuel A. Woodward, Fort Worth, and secretary-treasurer, Dr. Andrew B. Small, Dallas.——The Texas Alumni of the University of Pennsylvania organized an association at Dallas, May 11, and elected Dr. Jacob M. Frazier, Belton, president, and Dr. Marion P. Stone, Dallas, secretary.——Graduates of medical colleges of Louisville, Ky., practicing in Texas, met at Dallas, May 11, and organized an alumni association with an initial membership of fifty. The following officers were elected: Dr. James R. Lancaster, Granbury, president; Drs. William C. Crutcher, Mount Vernon, and Samuel E. Milliken, Dallas, vice-presidents; and Dr. Albert M. Gantt, Dallas, secretary.

Society Meetings.—Walker County Medical Association was organized in Huntsville, May 6, with an initial membership of seven. Dr. William E. Fowler, Huntsville, was elected president, and Dr. Leonard H. Bush, Huntsville, secretary-treasurer. ——At the annual meeting of Burleson County Medical Society, held in Caldwell, April 27, Dr. James P. Oliver was elected president and delegate to the state association; Dr. Joseph W. Matthews, vice-president, and Dr. Oscar Krueger, secretary-treasurer, all of Caldwell.——At the meeting of Brazoria County Medical Society, April 24, the following officers were elected: President, Dr. Samuel B. Maxey, Angleton; vice-president, Dr. C. C. Hampil, Perry Landing, and secretary-treasurer, Dr. D. C. DeWalt. The society starts out with a membership of twelve.——The physicians of Fort Bend County met in Richmond recently and organized a county medical association, and elected the following officers: Dr. James C. Johnson, Richmond, president; Dr. J. B. Turner, secretary-treasurer, and Dr. J. Mark O'Farrell, Richmond, delegate to the state association.——At the annual meeting of Webb County Medical Society, held in Laredo, May 5, Dr. Edward H. Sauvignet was elected president; Dr. Henry J. Hamilton, secretary-treasurer, and Dr. Albert W. Wilcox, delegate to the state association, all of Laredo.

VIRGINIA

Personal.—Dr. William W. Murray, Suffolk, has been appointed local surgeon for the Southern Railway.——Dr. John Augustine English Eyster, University, has accepted the chair of physiology in the University of Wisconsin.——Dr. Thomas J. Hughes, Saltville, has returned from Europe and located in Roanoke.

Commencement Exercises.—The Medical College of Richmond, Va., celebrated its annual exercises, May 18. Dr. Lyon G. Taylor, president of William and Mary College, delivered the doctorate oration and Dr. Simon Baruch, New York City, delivered the address before the alumni on "Some Therapeutic Lessons from Half a Century's Practice." A class of forty-six was graduated.——University College of Medicine, Richmond, held its annual commencement exercises May 17. Addresses were delivered by Major C. Hemphill, editor of the Richmond *Times-Despatch*, and the president of the college, Dr. Stuart McGuire. A class of 25 was graduated.

Society Election.—The semi-annual meeting of the Northern Neck Medical Association was held in Heathsville, April 28, and the following officers were reelected: President, Dr. Andrew C. Fisher, Emmerton; vice-presidents, Drs. C. T. Pierce and Loren E. Cockrell, Redville; secretary, Dr. Robert O. Lyell, Warsaw, and treasurer, Dr. Walter N. Chinn, Hague.——At the annual meeting of Alexandria Medical Society, Dr. Samuel B. Moore was elected president; Dr. Robert L. Wilkins, secretary, and Dr. Llewellyn Powell, treasurer.——The physicians of Alleghany County met in Clifton Forge, May 3, and organized a county medical society, with initial membership of ten. Dr. John C. Wysor, Clifton Forge, was elected president; Dr. Orville L. Rogers, Covington, vice-president; Dr. Courtney Edmond, Clifton Forge, secretary, and Dr. John W. Wallace, Covington, treasurer.

WASHINGTON

Used Mail to Defraud.—For using the mail in connection with a scheme to defraud, the managers of the Davis Medical Institute, Spokane, are said to have been sentenced to thirty days' imprisonment in jail and to pay a fine of $500.

Illegal Practitioners Arrested.—Detectives in the employ of the State Medical Board, operating under the direction of the prosecuting attorney of Seattle, have arrested eight alleged illegal practitioners of medicine, chiropody and osteopathy, including two Chinamen.

New Hospitals.—The cornerstone of the new buildings for the Providence Hospital, Seattle, was laid with appropriate ceremonies, May 1. Since the hospital was organized in 1878, more than 65,000 patients have been cared for by the institution.——The contract for the new two-story annex to the Pierce County Hospital, Tacoma, has been awarded. The building will cost about $4,000.

GENERAL NEWS AND COMMENT

Pension for Yellow Fever Victim.—As a reward for his services in the study of yellow fever, John Kissinger of Indiana, formerly private in the U. S. Army, was granted an annuity of $1,500 by the United States Senate.

Laryngologic Officers.—The secretary of the American Laryngological, Rhinological, and Otological Society writes that the Dr. Dudley noted in THE JOURNAL, May 14, as one of the vice-presidents-elect should be Dr. William H. Dudley, Los Angeles, Cal., and not William F. Dudley, Brooklyn.

Meeting of Railway Surgeons.—The third annual convention of the Association of the Norfolk and Western Railway was held in Norfolk, Va., May 4. Dr. Southgate Leight, Norfolk, was elected president; Dr. Sparrell S. Gale, Roanoke, first vice-president, and Dr. John R. Garrett, Roanoke, secretary-treasurer.

The Exceptional Child.—The National Association for the Study and Education of Exceptional Children held its first annual conference at New York University, April 21 and 22, under the presidency of Thomas H. Balliet, Ph.D., dean of the New York University School of Pedagogy. The session topics were "The Recognition of the Problem of the Exceptional Child," "Phases of Exceptional Development," and "The Perspective of the Problem of the Exceptional Child."

Confederate Surgeons Hold Meeting.—The thirteenth annual meeting of the Association of Medical Officers of the Army and Navy of the Confederacy was held in Mobile, April 26 and 27, under the presidency of Dr. Gustavus B. Thornton, Memphis, Tenn. Dr. Edwin D. Newton, Atlanta, was elected president, and Dr. A. A. Lyon was reelected secretary-treasurer.

American Museum of Safety.—The American Museum of Safety has opened permanent museum headquarters in New York, for demonstrations under power of safety devices to prevent industrial accidents. The museum is for the benefit of employers of labor in factories and industrial establishments and for the public generally, as a means of education in the matter of accident prevention. Approximately, 500,000 persons were killed or maimed in industrial pursuits in the United States during 1909, and 50 per cent. of these accidents undoubtedly were preventable. In a large steel plant employing 6,000 men, there were 40 fatalities in 1906. After installing safety devices there were only 12 fatalities in 1909 in the same establishment which then employed 7,000 men. The American Museum of Safety is an organization doing a practical humanitarian work and should be supported in every way.

Meeting of Far Eastern Association of Tropical Medicine.—The first biennial meeting of the Far Eastern Association of Tropical Medicine was held in Manila beginning March 5. Delegates were present from governments and medical organizations from nearly every country and colony of the Far East—the Indias, Ceylon, China, Japan, New Zealand, and the Philippine Islands. The association held eight sessions and continued until March 14. The convention was a successful one, and the *Bulletin of the Manila Medical Society*, says that never before have so many representative men from so many political entities gathered in conference in the tropics for the purpose of discussing the sanitary prob'ems peculiar to warm climates. Heretofore such large and important meetings have been held in temperate climates away from the environment where the practical side of the questions under discussion could not be made part of the proceedings. Dr. Paul C. Freer, Manila, was president of the association.

Alumni Entertainments at St. Louis.—The following is a partial list of alumni gatherings to be held June 7, 1910, during the session of the American Medical Association at St. Louis. *Alumni are asked to record their names, either at the Coliseum or at the Southern Hotel or elsewhere, as specified below, between 9 a. m. and 5 p. m., on Tuesday, June 7.* The recording at the Southern Hotel will be at a desk, which will be easily found in the lobby.

BARNES UNIVERSITY, MEDICAL DEPARTMENT.—Registration at Southern Hotel lobby. Seventeenth annual banquet at Planters Hotel, 8 p. m.

COLLEGE OF PHYSICIANS AND SURGEONS (COLUMBIA UNIVERSITY, NEW YORK).—Registration at Southern Hotel lobby. Reunion Tuesday. Particulars to be announced.

HARVARD UNIVERSITY MEDICAL SCHOOL.—Registration at Southern Hotel lobby. Dinner at the University Club, 7:30 p. m., June 7.

JEFFERSON MEDICAL COLLEGE.—Registration at Southern Hotel lobby. Banquet to be announced later. Information at registration desk or communicate with Dr. A. P. Munsch, 1239 Kingshighway, St. Louis.

NORTHWESTERN UNIVERSITY, SCHOOLS OF MEDICINE, DENTISTRY AND PHARMACY.—Registration at exhibit in Coliseum, 9 a. m. to 5 p. m., Tuesday, June 7. Banquet at Planters' Hotel, 7:30 p. m. Tickets for banquet at registration desk, or communicate with Dr. William Engelbach, Humboldt Building, St. Louis.

RUSH MEDICAL COLLEGE.—Registration at Southern Hotel lobby. Dinner to be announced.

ST. LOUIS UNIVERSITY MEDICAL DEPARTMENT.—Registration at exhibit in the Coliseum, 9 a. m. to 5 p. m., Tuesday, June 7. Banquet at Jefferson Hotel at 8 p. m. Tickets at registration desk, or communicate with Dr. P. H. Swahlen, Metroplitan Building, St. Louis.

TULANE MEDICAL SCHOOL.—Registration at Southern Hotel lobby. Banquet at Jefferson Hotel, 7:30 p. m. Tickets for banquet at registration desk or communicate with Dr. H. J. Scherck, Century Building, St. Louis.

UNIVERSITY OF NASHVILLE AND TENNESSEE.—Headquarters and registration, Rooms 80, 82 and 84, Southern Hotel, 9 a. m. to 5 p. m., Tuesday, June 7. Dinner to be announced.

UNIVERSITY OF MICHIGAN.—Registration at Southern Hotel lobby. Reunion planned.

VANDERBILT UNIVERSITY MEDICAL DEPARTMENT.—Headquarters and registration at the American Hotel, Seventh and Market streets. Reunion and banquet at American Hotel, 7 p. m..

WASHINGTON UNIVERSITY MEDICAL DEPARTMENT.—Registration at Southern Hotel lobby. Smoker for alumni, including Missouri Medical College and St. Louis Medical College, Tuesday, June 7, place to be announced.

CANADA

School of Anatomy Incorporated.—The Hamilton School of Anatomy has been incorporated by Drs. Ingersoll Olmsted, Archibald E. Mallach, and Alexander B. Osborne.

Unlicensed Practitioner Fined.—R. G. Galbraith, Spring Creek, Sask., is reported to have been found guilty of practicing medicine without a license and fined $50 and costs. The prosecution was undertaken by the College of Physicians and Surgeons of Saskatchewan.

Roddick Bill Held Over.—At the recent session of the federal parliament nothing was done toward amending the Canada Medical Act, known as the Roddick Bill. Action is said to have been deferred on account of solicitations from the medical council of British Columbia.

Medical Graduates Receive Diplomas.—At the commencement exercises of the Western Medical School, London, May 2, diplomas and medals were distributed to the graduating class by Dr. Robert Ferguson. Dr. Walter H. Moorhouse presided at the convocation.

Society Meeting.—At the annual meeting of the Ottawa Medical and Chirurgical Society, April 1, Sir James A. Grant, M.D., was elected honorary president; Dr. Thomas Gibson, president; Dr. Clarence H. Brown, first vice-president; Dr. John D. Courtenay, second vice-president; Dr. F. W. C. Mohr, secretary; Dr. Arthur S. McElroy, treasurer; Dr. Robert Law, librarian, and Dr. Warren S. Lyman, curator.

Dominion and Province Societies to Meet.—The forty-third annual meeting of the Canada Medical Association will be held in Toronto, June 1-4, under the presidency of Dr. Adam H. Wright, Toronto. The entertainment provided includes a smoking concert, and excursions to Niagara Falls and Guelph.——The Manitoba Medical Association will hold its annual meeting in Winnipeg May 26 and 27.——The annual meeting of the British Columbia Medical Association will be held in Vancouver, August 16 and 17, under the presidency of Dr. R. W. Irving, Kamloops.

Personal.—Dr. Charles F. Martin, Montreal, has returned from the Mediterranean.——Dr. John W. Stirling, Montreal, has returned from Europe.——Dr. John T. Fotheringham, Toronto, has returned from a trip to Jamaica.——Dr. Frederick A. Clarkson, Toronto, has gone to Germany for the summer.——Dr. George R. McDonagh has returned from the south of France.——Dr. E. A. McCullough, Toronto, has been appointed superintendent of the Sanatorium for Tuberculosis at London, Ont.——Dr. Albert A. McDonald has been elected president, and Dr. W. Harley Smith, secretary of the Academy of Medicine, Toronto.——Dr. Wesley Mills, professor of physiology in McGill University, has resigned.

Reunion of McGill Graduates.—The opening of the new medical buildings for McGill University, June 6 and 7, will be a notable event as more than 500 graduates from all parts of the world are expected to congregate in honor of their alma mater. On the first day an informal luncheon will be given at McGill Union by the teaching staff of the university; in the afternoon, the convocation will be held; in the evening the new building will be opened, and a conversazione will be given by the governors of the university. On the second day, clinics and demonstrations will be given in the morning and afternoon in hospitals and laboratories; class reunions will be held and a banquet will be given in the evening by the members of the faculty of the medical department to the alumni.

FOREIGN

Memorial Meeting for Pflüger in St. Petersburg.—A special meeting of the national medical Russian association was held recently at St. Petersburg in memory of the late Professor Pflüger of Bonn, the physiologist. The address was made by Professor Pawlow.

Wölfler Festschrift.—The pupils and friends of Professor Wölfler of Prague presented him last month with a *Festschrift* in the form of a special volume of the *Beiträge zur klinischen Chirurgie* containing the works of his pupils. The occasion was his sixtieth birthday and the twenty-fifth anniversary of his incumbency of the chair of surgery.

Circulation of German Medical Weeklies.—Some interesting data are found in the current number of the Press Directory issued by a leading advertising agency in Germany. It states that there are 352 periodicals published in Germany, Austria and Switzerland on the medical and allied sciences. The *Münchener medizinische Wochenschrift* heads the list of German medical journals with a certified circulation of 12,000 copies. This is followed by the *Deutsche med. Wochenschrift* with a circulation of 9,500, the *Medizinische Klinik* with circulation of 9,000, and the *Berliner klinische Wochenschrift* with a circulation of 4,000. In Austria the *Wiener medizinische Wochenschrift* has a circulation of 3.000, and the *Wiener klinische Wochenschrift*, a circulation of 2.400. The total circulation of these six great weeklies is thus stated to be 39,900.

LONDON LETTER

(From Our Regular Correspondent)

LONDON, May 7, 1910.

Women as Resident Medical Officers in General Hospitals

The question whether women should be eligible for appointment as resident medical officers in general hospitals, where they will have to deal with all sorts of emergency cases in male patients, such, for example, as retention of urine by stricture, has been a burning question for some time in this country. Recently the board of one of the greatest of the provincial hospitals, the Manchester Royal Infirmary, decided not to appoint medical women to these posts—a decision which has aroused considerable criticism from both lay and medical sources. A meeting of the Medico-Ethical Society of Manchester was held to discuss the subject. Some 20 medical women of the Northern Association of Medical Women attended by invitation. The case for the appointment of women was ably stated by Dr. Margaret Smith, inspector of midwives in Manchester. She outlined the history of medicine as a profession for women in this country since the admission of the first woman to the Medical Register in 1859. The facilities now offered to women for the study of medicine were now so good, she said, that on the whole they compared favorably with those of men. But after graduation their opportunities were inferior. However, they were improving. Women's attempts to get experience in the form of general hospital work were met with such objections as "lack of accommodation," "woman's inability to agree with ward sisters," objections which were put at their true worth in one word—prejudice. The questions should be: Is woman a fit and proper person for appointment to a resident post in a general hospital? Does she possess the same qualities as entitle a man to hold the position? The answer depended on three things: record of work, experience and personal character. As to work, women's college records were often just as good as men's; as to experience, they were handicapped for senior posts, but for junior posts they had equal experience with men—namely, *nil*; as to character, women had the same common sense, kindness and physical capacity for work as men. Women had been found to get on with their colleagues just as well as men —neither better nor worse. It was personality, not sex, which mattered. It was said that women themselves object to a woman doctor, but they accepted them in practice. The argument that for a woman to attend a male was shocking to male modesty cut both ways. Ability and special skill were, after all, the whole basis on which medical attendance, by man or woman, depended. Sir William Sinclair, the well-known gynecologist, president of the society, insisted that in admitting women to medical schools they were necessarily admitted to all positions a male medical student or doctor could occupy. Although the meeting was well attended, there was no debate, for the reason that no one could be found to oppose the proposition. The immense change of opinion which has occurred is shown by the fact that the celebrated physician, the late Sir William Jenner, resigned from the council of the British Medical Association rather than agree to the admission of women to the association. This change is only a particular case of a more general one—the great advance of the movement in favor of the rights of women, i. e., the removal of all sex disqualifications.

The Cold Storage of Vaccine Lymph

The Medical Officer of the Local Government Board has issued an important report on the cold storage of vaccine lymph. During the past 12 months 400,820 charges of glycerinated calf lymph were issued from the board's laboratory (which supplies all the public vaccinators of the country). In primary vaccination the "case success" was 99.4 per cent., and the "insertion success" was 95.9 per cent., which shows that a high quality of lymph was maintained. Some time ago a preliminary report was published by Dr. Blaxall and Mr. Fremlin on the results of sustained subjection of glycerinated calf lymph to temperatures below freezing point. The present report contains further information on lymph kept in cold storage for periods of 2 years and 6 months, respectively. The 2-year-old lymph was found to be free from extraneous organisms and to give a "case success" of 97.8 per cent. and an "insertion success" of 91.4. Since July, 1908, the lymphs collected from two calves have been divided into two portions, one being placed in cold storage for 6 months and then issued to public vaccinators, the other being issued without being subject to a temperature below freezing. The former gave a case success of 99.6 per cent. and an insertion success of 96.7; the latter was issued 6 to 8 weeks after it was taken from the calves and gave a case success of 99.5 per cent. and an insertion success of 96.5. Thus the results in the two cases were practically identical, showing that the cold storage had not impaired the activity of the lymph. This result is important, as it shows that by cold storage a supply of lymph may be stored to meet any sudden expansion of demand which may arise by reason of an epidemic of smallpox.

BERLIN LETTER

(From Our Regular Correspondent)

BERLIN, April 28, 1910.

Annual Meeting of the Society for Internal Medicine

As usual the Kongress für innere Medizin was held in the latter part of April at Wiesbaden under the presidency of the Berlin clinician, Professor Kraus. As about 180 papers were on the program and only four days available for the meeting, ten minutes or less was assigned for the reading of most of the papers, which consisted of mere abstracts. To be sure, this brief time is not favorable for thoroughness, but no other method is practicable to dispose of the large number of papers. With the new regulations which were adopted at this meeting it will be possible in future to limit the number of papers and so diminish the confusion. The reading of papers before the congress which have been already presented or published in the journals—which has hitherto frequently happened—will thus be prevented. Furthermore, papers which are deemed unsuitable will be rejected by the decision of the executive committee. Moreover, the time for the announcement of papers is limited, so that no papers will be received later than two to three weeks before the beginning of the meeting. It would be very desirable if by these means the excess of papers should be diminished; possibly also the general publication of German works will be favorably influenced.

SPECIFIC DIAGNOSIS AND TREATMENT OF TUBERCULOSIS

This was the principal topic of this year's session; it was presented by Professor Schütz, professor in the Berlin veterinary school and for some years a co-worker with Robert Koch, and by Professor Penzoldt of Erlangen. According to Schütz the subcutaneous injection of tuberculin gives only 2 to 3 per cent. of failures in the diagnosis of bovine tuberculosis. The other tuberculin diagnostic methods have proved inadequate. Bovine tuberculosis has constantly increased in Germany. In 1904, 17.88 per cent. of the cattle slaughtered in the abattoirs were tuberculous, but in 1907 the number was 21.21 per cent.; from 50 to 70 per cent. of the older milch cows may be regarded as tuberculous. With reference to the treatment of bovine tuberculosis, the method employed by Bang in Denmark, of feeding calves only with boiled milk, has not proved efficient; neither has the method of preventive injections of Behring's bovovaccine or Koch-Schütz' tauroman given satisfactory results. According to the German law regarding infection of cattle, enacted in 1909, all cattle with open tuberculosis are slaughtered and compensation made to the owners. In this way Germany loses annually over $3,600,000.

Penzoldt said in regard to diagnosis that Bloch's method of inoculation of animals by injection into the skin of the abdomen and slight crushing of the inguinal glands had shortened the time required to obtain reliable results. A positive cutaneous reaction he regards as a sure indication of tuberculosis, but the negative reaction is often unreliable. He does not consider any one preparation of tuberculin as unconditionally the best; all preparations are founded on the same principle. He advises to begin with 0.01 c.c. and increase by Sahli's method, avoiding any severe reaction. A rapid progress to large doses is dangerous and, on the other hand, too small doses give no results. The success with tuberculosis serums is inferior to that obtained by the tuberculin treatment. Hygienic and dietetic measures should be thoroughly enforced. Penzoldt has employed a careful tuberculin treatment for twenty years and is well satisfied with the results. A decisive opinion regarding the value of tuberculin cannot yet be given, but the remedy is surely given a higher rank at present than fifteen years ago. This view was supported by most of the following papers and discussions. In addition there were some who gave unlimited praise to the remedy and others who denied it all curative power. Professor Jochmann recommends, in accordance with his experiments made in the Rudolf Virchow hospital under the direction of Koch, to begin with old tuberculin and to continue with bacillus emulsion. Strong reactions are to be avoided by using tuberculin that is derived from bacilli which have been cultivated on media that are free from albumin. The best result Jochmann obtained was in glandular tuberculosis. Professor Sahli repudiates the diagnostic tuberculin reaction on account of its danger. Prof. F. Klemperer recommends immunizing with bovine tubercle bacilli in man.

Payr of Greifswald reported some observations on a peculiar stenosis of the colon at the hepatic and splenic flexures caused by abnormally sharp kinks and adhesions. With acute occlusion from this cause the picture of mechanical ileus may be produced, and the chronic condition may lead to the assumption of a carcinoma of the colon. In acute cases subcutaneous injections of atropin are of service, but in very severe cases and chronic cases operation is indicated. Payr has operated 27 times within six years with 2 deaths in quite desperate cases.

SECONDARY ANEMIAS

A very interesting report was made by Professor Gerhardt of Basel on the "Origin and Treatment of Secondary Anemias." A large part of the discussion was devoted to the importance of oleic acid as a cause of secondary pernicious anemia, particularly that due to the bothriocephalus. No concord of opinion was reached. Professor Schauman of Helsingfors emphasizes the importance of constitutional taints for the development of bothriocephalus pernicious anemia. Therapeutically great reliance is still to be placed on treatment by arsenic and iron. The transfusion of healthy blood has not produced any positive success, and the same may be said of serum treatment.

VIENNA LETTER

(From Our Regular Correspondent)

Vienna, May 10, 1910.

Distribution of Tuberculosis Among Vienna Children

In a report of the board of health some interesting data as regards the presence of tuberculosis among school children in Vienna are given. There were altogether 220,000 children between the ages of 6 and 16 in the Vienna elementary schools, of whom only 16,000 were examined. They comprised the poorer classes in the workmen's districts and the figures given are therefore selective. A constant increase in tuberculosis can be noted with increasing age. Children 6 to 10 years old were found suffering from one-sided lung disease in 10 per cent.; on both sides in 4 per cent.; and from bone tuberculosis in 3 per cent. The ages of 10 to 10 showed 12 per cent. disease of one lung, 3 per cent. of both lungs, and 5 per cent. of other tuberculous infections, while in the ages 14 to 16 practically the same conditions prevailed. The mortality from tuberculosis increased from 3 per cent. of all deaths in the first years to 12 per cent. of all deaths of the age 14 to 16. For comparison, it may be stated that all deaths from measles, whooping-cough, scarlet fever and diphtheria combined also amounted to a little over 12 per cent. The grave danger to the public disclosed by these figures cannot be overestimated. The private societies engaged in fighting tuberculosis of children are absolutely unable to grapple satisfactorily with the problem, and state help is at present negligible. The appointment of school doctors is a mere trifle, unless the parents are enabled to make their sick children healthy. This is the aim of the report.

Report of the Antirabies Institute in Vienna

The institute for antirabies inoculations in Vienna has recently published its report for 1907 and 1908; the following figures are worth mentioning: During the period covered, 955 persons applied for treatment and 148 others, who came to the institute for the same purpose, were found to be in no need of prophylactic injections. Seventy-seven per cent. of all the persons treated had been bitten by dogs undoubtedly suffering from rabies; 15 per cent. were bitten by animals which showed suspicious symptoms, but in which diagnosis was not confirmed by post-mortem findings, and the remainder were bitten by dogs against which suspicion was aroused from the presence of rabies in the vicinity. Altogether, 429 children, 366 men and 160 women were treated. Only such persons were received as had suffered a bleeding injury from the bite. The mortality during the two years was 0.7 per cent. (6 deaths), and if all cases treated in the institute are considered, the mortality is the same, 0.7 per cent. of 3,572 (26 deaths). Another 13 persons died out of this number during the time of observation, but these deaths were due to other disease than rabies. The number of deaths from rabies in the entire empire during the two years was 20 (13 persons not inoculated, 6 inoculated, one died during treatment). Since the number of persons injured by animals is unknown, a comparison between cases of persons inoculated and not inoculated is impossible. The rule in the institutes is to keep the patients in hospital, sending them home only after a definite course of injections has been made. In some cases, home treatment is given. Of the number mentioned above, 248 were treated as out-patients. There are in this country only three institutes of this kind, the largest being in Vienna, and the public are quite aware of the danger incurred by being bitten by a dog, as the number of persons showed who applied for treatment simply out of fear of rabies.

Meeting of Austrian and Hungarian Pediatrists

A very interesting and novel congress took place recently (April 30 to May 1) in Vienna, when Hungarian and Austrian pediatrists held a common session, a thing thought impossible before from political reasons. The shortness of time did not permit this first meeting to be as successful as it might have been, since so many papers were brought in at the very last moment that the time for reading had to be limited. Professor Chrobak, after welcoming the congress, explained its aim, and showed how political differences of opinions made a halt before science. Professor Escherich spoke about the indications and results of specific treatment of infantile tuberculosis, which was extremely important in producing so high a mortality. Docent Dr. Preisich of Budapest detailed the clinical and pathologic findings in tuberculosis in infancy; Professor Kraus read a paper on the use of tuberculin in infants. Professor von Bokay of Budapest detailed his observations on chronic hydrocephalus, which he said could be influenced materially by repeated punctures of the brain ventricles; the metabolism of childhood was discussed by von Reuss, Neurath, Fuchs, and Necker, and the discussions following these papers showed that much good could be obtained from such exchange of ideas. It was resolved to make such common meetings a standing institution.

Pharmacology

CHINOSOL

Report of the Council on Pharmacy and Chemistry

Chinosol, a product for which the Parmele Pharmacal Company is the American agent, was the subject of a Council report which appeared in THE JOURNAL, Jan. 25, 1908. The company took exception to the findings in the report and requested that Chinosol be reexamined. The request was granted, and the referee who made the first bacteriologic examination of the product—and who in this report will be called Referee I—reinvestigated Chinosol. An independent examination also was made by an expert (Referee II) who was not a member of the Council. The reports of Referees I and II were submitted to a third referee (Referee III), who in turn transmitted them to the Council. Copies of the reports of the referees were also sent to the Parmele Pharmacal Company, which objected to certain of the findings. The report of Referee III, based on the reply of the company, and on the findings of Referees I and II, appears below. The objections raised by the company to the second report were replied to by the Council, and with its reply were sent the results of the investigations made in Europe by Schneider and Seligman and by Charles J. Martin which confirmed the findings of the Council. After considering this further evidence, the company modified its claims and the Council accepted Chinosol for inclusion in New and Nonofficial Remedies.[1]

W. A. PUCKNER, Secretary.

The Council on Pharmacy and Chemistry took up the consideration of Chinosol on its own initiative and published its report in THE JOURNAL, Jan. 25, 1908. The Parmele Pharmacal Co. requested a reconsideration of Chinosol on the ground that the preparation examined which bore the label of Franz Fritzsche & Co., Hamburg,[2] did not come from them, since it did not bear their label. The firm also submitted bacteriologic reports by Dr. W. H. Patterson and by the Lederle Laboratories of New York with findings that differed in certain important respects from those obtained by the investigation made at the instance of the Council, and expressed the desire to conform to the rules of the Council in the exploitation of the preparation. In its letter to the Council the Parmele Pharmacal Co. laid special stress on the report of the Lederle Laboratories, and stated that it felt confident "that your referee will find our tests confirmed in every instance and will not find confirmed his own tests, if he will use Chinosol bearing our label."

Assuming that there might be a difference in the two brands of Chinosol as claimed, and considering the fact that the company had been willing to alter, and had somewhat altered, its advertising matter, removing some of the objectionable features and had accepted to some extent the criticism of the Council's first report, the Council granted reconsideration, and Chinosol was resubmitted to the original referee, who will be called Referee I in this report. Referee I having completed his reexamination of Chinosol,[3] the product at the request of the company and under revised rules of the Council, was submitted also to a new referee, not a member of the Council, who acted essentially in a professional advisory capacity to the Council, and who will be called Referee II in this report.[3] The reports of both referees having been considered by the Council and preliminary action taken by it, the Parmele Pharmacal Co. was, in accordance with the rules of the Council, given an opportunity to examine the *findings* of the Council and the reports of its referees, and the company submitted statements in reply. These statements and the findings of its referees having been carefully considered, the Council reached the following conclusions in regard to the questions concerning Chinosol:

AN INTENSE ANTISEPTIC

In its first report the Council found that Chinosol "does possess considerable antiseptic action and that it is in this respect superior to carbolic acid. On this point the statements in the circulars[4] are essentially correct." The findings of both our referees in the present investigation confirm this conclusion. As regards *Staphylococcus pyogenes aureus* and *Bacillus typhosus*, Chinosol is a better antiseptic than carbolic acid and equivalent to mercuric chlorid as an antiseptic. The findings of our first report and the claims of the Parmele Pharmacal Co. on this point are thus confirmed. [It should be stated that Chinosol as now marketed is free from 30 per cent. inert matter—potassium sulphate—and is, therefore, proportionately stronger than the brands examined by the Council's experts.]

A VERY POOR GERMICIDE

While there was no dispute concerning the antiseptic action of Chinosol, the findings of the Council in regard to its germicidal action disagreed fundamentally with the claims made for it in this respect by the Parmele Pharmacal Co. and with the findings of their experts. While the company had withdrawn its most extravagant claims concerning the germicidal power of Chinosol, it still claimed in the report of the Lederle Laboratories that Chinosol was superior to carbolic acid, and that in its action on *S. p. aureus* it was, in weak acid broth, "stronger than bichlorid" (not under other conditions), and that in general Chinosol resembled more nearly the strength of bichlorid of mercury than it did that of carbolic acid. The three investigations made by our referees (two by Referee I and one by Referee II) lead to the definite conclusion that in aqueous as well as in acid broth Chinosol is much less effective as a germicide than is carbolic acid and vastly inferior to mercuric chlorid.[5]

[NOTE: The Parmele Pharmacal Company has now withdrawn its claim that Chinosol has superior germicidal power to either phenol (carbolic acid) or mercuric chlorid.]

DISTINCTION BETWEEN ANTISEPTIC AND GERMICIDE

The striking difference in these results from those reported by the Lederle Laboratories appears to be due essentially to the care taken by our experts to exclude the possibility of *antiseptic* action being mistaken for *germicidal* action (see the reports for details; the precaution consisted simply in inoculating *larger* volumes of culture medium in order to overcome by dilution the intense antiseptic powers of Chinosol). The validity of such precautions appears to be above question—the principle has been recognized and accepted by such authorities, for instance, as Martin and Chick, Riedel and Walker, and others in the field.

> *Martin and Cooper's Results:*—A letter received from the Parmele Pharmacal Company was handed to Referee II for an opinion, inasmuch as the letter quoted the results of Chick and Martin and attempted to show that these favored the stand taken by the Parmele Pharmacal Co. It was seen at once that the results of Chick and Martin in no wise supported the views of the company, but lest any error be committed in interpretation, Referee II wrote to Professor Charles J. Martin, F. R. S., director of the Lister Institute of Preventive Medicine, London, asking for an expression of opinion of the results of his own and Dr. Chick's work in the light of the quotation of the Parmele Pharmacal Co. Professor Martin's attention was also drawn to the fact that in their experiments with Chinosol the *antiseptic action* had possibly been overlooked.
>
> This letter was acknowledged and in a second letter Professor Martin wrote that Mr. A. E. Cooper, working with him, had repeated Referee II's observations on Chinosol and had confirmed the referee's results. Professor Martin expressed regret that he had omitted to ascertain in his first work (with H. Chick) whether Chinosol exhibited inhibition in such great dilution; a large number

---

[1] See page 1789. See also editorial comment, this issue.

[2] The Parmele Pharmacal Co. thought at the time the preparation used had been repacked by some American drug-house other than their own, and did not intend to question the product of Franz Fritzsche & Co.

[3] The reports of Referees I and II and the protocols of Cooper and Martin will appear in the reprint of the entire matter, which will be mailed on request if a stamped addressed envelope is sent. The matter will appear in full in the annual reports of the Council on Pharmacy and Chemistry.

[4] The circulars of the Parmele Pharmacal Co.

[5] In their work on the germicidal power of corrosive sublimate, Chick and Martin (Jour. Hyg., 1908, viii, 654), *in order to avoid* the further action of mercury carried over in combination with the bacteria remove it with hydrogen sulphid. As such a subsequent exposure to hydrogen sulphid—which reduces the germicidal efficiency of bichlorid—would, except in the case of disinfection, possibly of fecal discharges, not occur in *practice, this behavior* does not affect the efficiency of corrosive sublimate as a practical disinfectant ("The value of corrosive sublimate as a practical disinfectant remains unassailed."—Chick). The hydrogen sulphid treatment was therefore not used by our referees. It is quite different with Chinosol, whose antiseptic action can be *overcome* by subsequent dilution—such as is quite possible or even probable in practice.

of organic disinfectants had been examined by them without their coming across this phenomenon. At the time too, they were not concerned with determining the germicidal value of Chinosol.

The following tables are an abridgement[2] of the work and results of Mr. E. A. Cooper and Professor Martin:

SERIES I.

Organism used: *Staphylococcus pyogenes aureus*, broth culture 24 hours old. Several drops of this culture were deposited in the dilutions of phenol (carbolic acid) and Chinosol, and by means of a special pipette one drop containing 0.013 c.c. was carried over from each dilution to a tube containing 10 c.c. of broth and incubated.

Apparent Germicidal Results With Chinosol

Agent.	Dilution Strength.	Time of Exposure in Disinfectant (Growth Results). 15 Min.	30 Min.	Ultimate Dilution of Agent in 10 c.c. of Broth.
Phenol	7:1000	+	+	1:109,890
	9:1000	+	—	1: 85,470
	10:1000	—	—	1: 76,923
Chinosol ...	80:1000 up to 200:1000	— —	— —	1: 9,615 up to 1: 3,846

SERIES II

To eliminate the inhibitive or antiseptic action of Chinosol on *S. p. aureus*, one drop (0.013 c.c.) of the contents of the first broth tube was removed and deposited in a second one containing 10 c.c., and incubated.

Germicidal Action Absent

Agent.	Dilution Strength.	Time of Exposure in Disinfectant (Growth Results). 15 Min.	30 Min.	Ultimate Dilution of Agent in 10 c.c. of Broth.
Chinosol ...	80:1000 up to 200:1000	+ +	+ +	1:7,396,150 up to 1:3,958,460

Similarly using *Bacillus typhosus*, it was demonstrated that the antiseptic action of Chinosol was considerably less than on *S. p. aureus*, and germicidal action was absent.

It is, therefore, clear that what Chinosol could not effect on *S. p. aureus*, in strengths of 200:1000 parts, phenol (carbolic acid) accomplished in 10:1000 parts; this effectively demonstrates the superiority of phenol as a germicide over Chinosol.

Schneider and Seligman's Work:—Of particular interest and importance in this connection is the work of Schneider and Seligman in the laboratory of Proskauer, *Institut für Infektionskrankheiten*, Berlin (*Ztschr. f. Hyg. u. Infectionskrankh.*, 58, 412-40). These investigators recognized clearly the importance of *avoiding the mistaking of antiseptic action for germicidal action* in the examination of disinfectants, and write as follows concerning Chinosol: "With Chinosol also, to which a disinfecting power equal to that of corrosive sublimate is ascribed, we obtained poor results by the 'thread method.' Whereas, for instance, only a 10 per cent. solution of Chinosol was able to kill within an hour the staphylococci dried on the threads, the ordinary method of transfer of the mixture of bacteria and disinfectant in the culture medium gave the false appearance of killing the bacteria in approximately the same time already in 1 per cent. to 2 per cent. solutions. That this last result is due only to antiseptic action ('*Entwickelungshemmung*') need not be especially emphasized." Their results (*S. p. aureus* being used) are so characteristic of the question in dispute that they are reproduced here:

TABLE I

Antiseptic Action Not Avoided

Minutes	5	10	15	20	25	30
2 per cent............	—	+	—	—	—	—
3 per cent............	—	—	—	—	—	—

TABLE II

Staphylococci Threads; Antiseptic Action Avoided

Minutes	10	20	30	40	50	60
3 per cent............	+	+	+	+	+	+
5 per cent............	+	+	+	+	+	+
7 per cent............	+	+	+	+	+	+
10 per cent...........	+	+	+	—	—	—

The results obtained in Table I were obtained without using the precaution to prevent antiseptic action; those obtained in Table II are the results found when the threads were washed with dilute alkali to remove adhering Chinosol before transferring them to nutrient media. In another set of experiments carbolic acid was used, also with *S. p. aureus*.

TABLE III

Antiseptic Action Not Avoided

Minutes	5	10	15	20	25	30
Phenol 1 per cent......	+	+	+	+	+	+
Phenol 1.5 per cent....	+	—	—	—	—	—

TABLE IV

Threads Washed with Dilute Alkali; Antiseptic Action Avoided

Minutes	5	10	15	20	25	30
Phenol 2 per cent......	—	—	—	—	—	—

The Council thus was obliged to confirm its original findings that while Chinosol is a powerful antiseptic, it is a very poor germicide, and the claims made for it in this respect must be rejected. It may be added that the Council has considered the question of physicians being given reliable information as to each of these properties a fundamental one.

ITS NON-POISONOUS CHARACTER

In the Council's first report the evidence of T. Weyl was quoted questioning the claim made that the use of Chinosol is free from the dangers of poisoning. Weyl's evidence and reliability having been questioned by the firm and experimental evidence by the Lederle Laboratories submitted contradicting his conclusions, the Council had some experiments bearing on this question carried out by its own expert.[6] It finds that in so far as guinea-pigs and rabbits are concerned Chinosol is devoid of toxic power. The authority quoted in the first report is therefore found to be unreliable and Chinosol must be considered non-toxic.

CHEMICAL COMPOSITION OF CHINOSOL

In 1899 Rost-Sonntag showed (*Chem. Zentralbl.*, 1899, ii, 396, and *Arb. a. d. k. Gsndhtsamte*, xv, 288-301), that Chinosol was a mixture. In its first report the Council confirmed the conclusions of Brahm, working in the physiologic institute of the University of Berlin, that Chinosol is not a sulphonate of oxyquinoline, as represented by the promoters of Chinosol, but a double salt or mixture of its sulphate with potassium sulphate. The result of these findings was accepted by the Parmele Pharmacal Co. and the correction made in its subsequent publications; the original error, according to the firm, was due to its accepting the statement of the U. S. Dispensatory, i. e., that Chinosol is an oxyquinoline sulphonate as authoritative in the matter. Chinosol is now no longer marketed as the double salt or mixture of oxyquinoline sulphate and potassium sulphate, but as pure normal (neutral) oxyquinoline sulphate $(C_9H_7NO)_2H_2SO_4$.[7]

ANTISEPTIC ACTION VS. GERMICIDAL ACTION

It seems of the greatest importance to the Council that antiseptic power be not mistaken for germicidal power and that physicians should be correctly informed as to these properties of disinfectants[8] recommended to them, so that they may decide for themselves in every given case which action they wish to produce. This seems especially important in the case of a substance, which, according to the findings in three expert examinations on the part of the Council, has very poor germicidal power, not at all comparable with that of bichlorid of mercury, as had been claimed by the Parmele Pharmacal Co. In view of this the Council ordered the publication of this report and refused to accept Chinosol for admission to "New and Nonofficial Remedies" until the claims made for its germicidal action had been modified in accordance with its findings.

[Note: The Parmele Pharmacal Company has re-submitted Chinosol with the advertising matter revised in accordance with the findings of the Council. All objectionable claims having been eliminated the Council reconsidered the product and accepted Chinosol for admission to New and Nonofficial Remedies.]

---

[6] These appear in the report of Referee II; see footnote 2.

[7] Zernik: Apoth.-Ztg., 24, No. 63, p. 568.

[8] For example, in the disinfection of hands, instruments, linen or silk threads, etc., germicidal and not antiseptic power would be desired. Chinosol solution as dilute as 1:1000 had been recommended for these purposes. A glance at the tables, either of the referees or of Schneider and Seligman, will show the danger of assuming that complete disinfection is accomplished by such solutions in a reasonable length of time.

ASPIRO-LITHINE

Aspiro-lithine is another comparatively new example of the custom of proprietary manufacturers in putting forward old drugs under a new name and with them bidding for the favor of physicians. An inquiry has been received concerning this mixture. It is prepared by McKesson & Robbins and is said to contain in each tablet 5 grains of acetylsalicylic acid (aspirin) and 2½ grains of acid citro-tartrate of lithium. It is recommended for all the purposes for which acetylsalicylic acid is commonly used, and on account of the lithium added is claimed to have much greater virtues than either of these drugs alone or of both combined.

We had hoped that the time had passed for reputable houses to employ such time-worn methods, but probably they will not stop so long as physicians encourage them by continuing to use such preparations. Acetylsalicylic acid is a good drug, whose value is pretty well known. It is further known that lithium salts do not possess any great medicinal virtue. Just what acid citro-tartrate of lithium may be is hard to tell, for chemistries do not recognize such a substance. The name presumably is intended to hide the real nature of the preparation.

But if there be any advantage in combining lithium salts with acetylsalicylic acid in a prescription, it is a simple proposition and requires no great skill, either on the part of the physician who writes the prescription or on the part of the druggist who puts it up, and such mixtures as aspiro-lithine, with the exaggerated claims made for them, should be avoided in the physician's prescribing.

Correspondence

Medical Biographical Data Wanted

To the Editor:—In my Cyclopedia of American Medical Biography, now practically ready for press, there are a few dates still lacking.

Douglas, Richard, Tennessee, parentage and birth place.
Faget, Jean C., New Orleans, date of death.
Pallen, Moses, St. Louis, parentage and birth place.
Denison, Charles, Denver, parentage and birth place.
Guthrie, Samuel, Chicago, date of death.
Van Dyck, Cornelius, Syria, date of birth and death.
Litton, Abraham, Tennessee, date of birth and death.
Gregory, Elisha H., St. Louis, date of death.
Burroughs, Richard B., Florida, date of death.
Cheever, Aug. C., Boston, date of death.
Eve, Joseph A., Georgia, wife; death date.
Entrikin, F. W., Ohio, date of death.
Etheridge, J. H., Chicago, date of death.
Howard, R. P., Canada, date of birth.
Gilmer, George, Virginia, date of death.
Martin, Solomon C., St. Louis, date of death.
Cheever, Abijah, Boston, date of birth and death.
Jones, John, New York City, date of death.

If any readers could help me with these they would receive the warm thanks of,

Yours faithfully,
HOWARD A. KELLY, Baltimore.

Pituitary Extracts in Hay Fever, Asthma, Etc.

To the Editor:—The period of so-called "rose cold" or "vernal hay fever"—i. e., vernal, pollenogenic, angioneurotic edema of the air passages—is approaching, or with certain patients, here. Referring to my observations in 1898 concerning the use of adrenal preparations in this disorder and in asthma (since confirmed throughout the world) I wish now to ask physicians to use preparations of the pituitary gland, and more especially of the infundibulum or posterior lobe. There are at least two, and possibly several, good commercial preparations now available.

From the recoveries which I have observed to follow their use in Quincke's edema, asthma, recurrent erythema and other angioneuroses, as well as their effects in "opening" the nasal passages, I should expect them to be superior to the adrenal preparations in all varieties of hay fever. The action is slower, but more persistent.

The pituitary extracts may be used both topically and systemically. While more effective by hypodermic injection, they also produce clinical results when administered by the mouth—another advantage over the adrenal extracts.

I shall be much obliged for reports by letter or publication of the experience of those adopting this suggestion.

SOLOMON SOLIS COHEN, Philadelphia.
1525 Walnut Street.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

VALUE OF TETANUS ANTITOXIN

To the Editor:—Has the efficiency of antitetanic serum in the treatment of tetanus been sufficiently demonstrated to merit its use in that disease with confidence of positive results?

C. A. ANDERSON.

ANSWER.—It has not been found that antitetanic serum has any particular effect on the symptoms of tetanus because these appear as the culmination of the disease when it is too late for anything to have much effect. As a prophylactic, however, antitetanic serum is markedly efficient, especially if accompanied with free opening of the wound and removal of foreign matter. It is important to prevent this foreign matter and the tetanus germs from being sealed up at the bottom of the wound, which often heals superficially. The efficiency of antitetanic serum has secured for it a position in New and Nonofficial Remedies and the Committee of the Section on Pathology and Physiology recommends its inclusion in the Pharmacopeia. The report of this committee appeared in THE JOURNAL April 23, 1910, page 1389.

SOIL POLLUTION AND DISPOSAL OF HUMAN EXCRETA

As further communications have been received concerning soil pollution and disposal of human excreta and wastes by the septic-tank method, about which a query and answer appeared in THE JOURNAL, April 23, an additional note on these subjects may be of interest.

In the weekly *Public Health Reports* of the U. S. Public Health and Marine-Hospital Service, April 29, Dr. C. W. Stiles has an article which may be obtained in reprint, on the subject of soil pollution and the sanitary privy, from which extracts are given below.

The importance of the prevention of soil pollution is apparent when it is remembered that diseases having their focus of infection in the intestinal and urinary systems, such as typhoid fever, hookworm disease, eelworm infection, tapeworms, Cochin China diarrhea, amebic dysentery, bacillary dysentery, etc., can be greatly reduced or eradicated by the prevention of such pollution. Dr. Stiles says that it is common knowledge that nearly all animals harbor parasites in their intestinal canals. The eggs are passed in the droppings and reinfect live stock; farmers have learned that animals kept on the same pasture year after year will not thrive on this account. Human beings are also infected with many parasites, and where no sewer systems exist soil pollution must be prevented by the disposal of human dejections in sanitary privies or by the septic-tank method.

Dr. Stiles' paper, while covering much the same ground as the article in THE JOURNAL of April 23, goes more fully into details as to the location and construction of sanitary privies and disinfection and disposal of the excreta. The article gives illustrations of such privies, using a receptacle in the form of a can or tub, with top-soil, lime, water and oil, and other materials for deodorizing, disinfecting or destroying the excreta. Full directions are given for building such a privy. It is a good plan to have a double set of tubs so that one set can be removed, treated with the disinfectant, covered and allowed to stand for a week before emptying to allow time for the destruction of the germs, or to allow fermentation to take place when no disinfectant is used. Dr. Stiles says that until it is determined with certainty how long parasites and germs or their spores may live under the various methods of treatment of the excreta mentioned, it is better to bury all human discharges at least 300 feet away and down hill from any well or spring. It would be better to burn such material, and in one instance this was done in the following way: The privy vault was built of cement and the building above hinged to the foundation. Kindling and straw were placed in the bottom of the vault, and each week the upper structure was tipped over—away from danger of catching fire—oil thrown into the vault and the material burned up. If used for fertilizer it should be plowed under and not used on crops of vegetables which are to be eaten raw.

The vacation season will soon be here and many people will spend the summer in temporary residences or camps. The matter of the disposal of waste is important. The human excrement may be disposed of by the dry-earth method already described. Kitchen slops attract flies and afford breeding-places for mosquitoes. A simple and inexpensive way to dispose of this form of waste is to dig a hole in porous earth three feet deep, with short tunnels running off from each side. The pit may then be filled with broken rock, sticks and brush and covered with a top mat of pine needles or other finely divided material. Coarse refuse is screened out and burned in the camp fire each day and the rest of the slops will take care of themselves in the slop pit without odor or inconvenience. The pit should be surrounded by a frame covered with fine mesh cheese-cloth. Dry garbage is disposed of most effectively by frequent burning.

The septic-tank process of disposal of sewage depends on the breaking down of the solid, organic matter of the sewage into simpler substances by the action of anaerobic, putrefactive or liquefying bacteria. It has been found that from 50 to 75 per cent. of the solid matter is destroyed by the process, and where the effluent is discharged into a stream twice as much septic as raw sewage will be received before the point of pollution is reached which will cause a nuisance. The effluent may also be discharged into contact beds, where it is oxidized by aerobic bacteria or into the soil through subsurface pipes.

The details of the process may be understood by describing the construction and operation of a septic tank designed for use by private individuals having in their houses a gravity, compressed-air or other water-supply system. This description, as well as the notes on the disposal of camp garbage, is from the March, 1910, *Bulletin of the California State Board of Health*. It has been found that the bottom of the tank should have at least one square foot of surface for each person in a family. It may be made of either concrete or wood, 4 feet deep and 4 feet wide and of sufficient length to provide the proper surface capacity. It should be located some little distance from the house, connected therewith by a 4-inch vitrified drain tile, which should enter at the top and continue at a right angle to within a foot of the bottom. The outlet pipe on the opposite side of the tank should be of 2-inch tile, located 2 feet from the bottom. The tank may be buried in the ground and should perhaps be covered and have a small vent-pipe in the top. A tight cover is not essential. A baffle or partition 2 feet high, running the full length of the tank should be placed on the bottom 1 foot or less from the side of the inlet, and another suspended edgewise from the top of the tank an equal distance from the side of the outlet and reaching within a foot of the bottom. These baffles insure a uniform distribution of the sewage. This completes the tank, except that the outlet should be provided with a galvanized iron weir of one gallon capacity connected with the outlet tile by means of a galvanized iron pipe, permitting a continuous outward flow. The outlet pipe should be continued into a surface contact bed, a stream, or by loose-jointed branched tile, having a total length of at least 200 feet underneath the surface to conduct away the effluent. Subsurface irrigation is successful only in porous soil. This tank will take care of sewage from the toilet, bathroom, kitchen and the laundry-tubs.

The sewage flows from the house into the septic tank and is held there by the outlet weir for ten or twelve hours. During this time the sewage is worked over by the anaerobic bacteria and broken up, the heavy, inorganic portions sinking to the bottom, the lighter portion rising to the top and forming a feathery mat. but most of it is broken up into gases and materials which dissolve in the water and are carried off. A tank with sufficient area to work successfully need not be cleaned of sludge for three or four years. This tank will cost from $25 to $30. This method is applicable to small cities or towns having a sewer system, and is successful where sufficient area of tankage is provided. The effluent, however, must be discharged into streams or be treated by chemical or contact bed methods.

The Public Service

Medical Department, U. S. Army

Changes for the week *ended May 21, 1910*:

Long, Charles J., dental surgeon, ordered to Fort Thomas, Rhode Island, *for duty*.

The following named officers of the Medical Corps will report in person, June 20, 1910, to Lieutenant Colonel Henry P. Birmingham, Medical Corps, president of the examining board at the Army Medical Museum Building, Washington, D. C., for examination to determine their fitness for promotion: Majors Henry D. Snyder, Philip C. Bates, Allen M. Smith, Joseph T. Clarke, Merritte W. Ireland, Henry C. Fisher, Henry A. Shaw, Francis A. Winter.

Fauntleroy, P. C., *major*, granted 10 days' leave of absence.

Vaughan, Victor C., 1st lieut., M. R. C., will proceed from Ann Arbor, Mich., to this city, for the purpose of delivering the address to the graduating class at the Army Medical School on May 31, 1910, and on the completion of this duty will return to his home.

Phalen, James M., *capt.*, *ordered* to Columbus Barracks, Ohio, for *duty*.

Love, Albert C., capt., will repair to this city and report in person to the Surgeon General of the Army, for duty in his office.

Duncan, William A., *capt., relieved from duty* at Army General Hospital, San Francisco, and from *observation* and treatment, Walter Reed General Hospital, Washington, D. C., and ordered to Vancouver Barracks, Wash., for duty.

Cutliffe, William O., *1st lieut.*, M. R. C., granted leave of absence for 1 month.

Miller, Albert L., 1st. lieut., M. R. C., relieved from temporary *duty at Fort Robinson*, Neb., *and* to return to station at Fort Meade, S. Dak.; granted 24 days' leave, *to take effect about* May 20, 1910.

Hoff, John Van R., col., *detailed as* instructor in military hygiene at the Camp of Instruction for infantry officers of the organized militia, State *of Pennsylvania*, to be held *at* Mt. Gretna, Pa., commencing May 17, 1910.

Pipes, Henry F., capt., is assigned to the command of the one-half of Co. C, Hospital Corps, to participate in the military tournament at Nashville, Tenn., June 19 to 26, 1910, the camp of instruction at Chickamauga Park, Ga., July 5 to Aug. 2, 1910, and camp of instruction at Fort Benjamin Harrison, Ind., Sept. 1 to 30, 1910.

Bradley, John R., 1st *lieut.*, M. R. C., *ordered to* duty with Battery E, 5th Field Artillery, from Fort Leavenworth, Kan., to Sparta, Wis.

Fauntleroy, P. C., reports on 10 days' leave of absence.

DeLaney, M. A., capt., ordered to proceed to Philadelphia, on official business pertaining to the Medical Department.

The *following* assignments of officers of the Medical Corps to duty at the camp of instruction to be held at Gettysburg, Pa., during the month of July, 1910, *are ordered*: *Major* E. E. Parsons, *to command* stationary hospital; Major Charles R. Reynolds, to be medical inspector; *Captain George P. Pood, to be sanitary officer*, assistant to the medical inspector; Captain William B. Davis, to be sanitary officer, assistant to the medical inspector.

Banister, *John* M., col., granted 4 months leave of absence, to take effect about Sept. 1, 1910.

Harris, Jesse R., capt., ordered to the *Army General Hospital*, *San* Francisco, for observation and treatment.

Gunckel, George L., dental surgeon, reports *for* temporary duty at Fort Barrancas, Fla.

Medical Corps, U. S. Navy

Changes for the week *ended May 21, 1910*:

Kaufman, J. B., P. A. *surgeon*, *commissioned* passed assistant surgeon from March 24, 1909.

Dodge, A. H., asst.-surgeon, detached from the *California* and *ordered to continue treatment* at the Naval Hospital, Mare Island, Cal.

Halton, E. P., acting asst.-surgeon, appointed acting assistant-surgeon from May 16, 1910.

U. S. Public Health and Marine-Hospital Service

Changes for the week ended May 18, 1910:

Trask, J. W., asst.-surgeon general, directed to proceed to Detroit and Lansing, Mich., and Harrisburg, Pa., on special temporary duty.

Woodward, R. M., surgeon, granted 7 days' leave of absence from May 15, 1910, under paragraph 189, Service Regulations.

Cobb, J. O., surgeon, leave *granted for 7 days from May 7, 1910*, amended to read 5 days from May 7, 1910.

Stimpson, W. G., surgeon, granted 20 days' leave of absence from May 15, 1910.

Anderson, John F., P. A. surgeon, directed to proceed to Mariette, Pa., *on special* temporary duty.

Ridlon, Joseph R., asst.-surgeon, relieved from duty *on the U. S. Revenue Cutter Seneca*, and directed to proceed to *Port Townsend*, Wash., and report to the commanding officer of the U. S. Revenue Cutter *Manning* for duty.

Gammon, William H., acting asst.-surgeon, granted 4 months' leave of absence, without *pay*, from May 15, 1910.

Hamilton, H. J., acting asst.-surgeon, granted 10 days' leave of absence from May 8, 1910.

Wallace, C. R., acting asst.-surgeon, granted 6 days' leave of absence from May 15, 1910.

Hobdy, W. C., P. A. surgeon, resignation *accepted by the* President, *effective May 31, 1910*.

Marriages

Milo Tripp Easton, M.D., to Miss Mary Helen Blackburn, both of Peoria, Ill., May 18.

Louis L. Hoff, M.D., Roxbury, Boston, to Miss Bessie Climan of Hartford, Conn., May 7.

James Thomas Taylor, M.D., to Miss Emily Louise Rankin, both of Reidsville, N. C., May 5.

Jesse W. Taft, M.D., Waukesha, Wis., to Miss Emma Leora Einsel of Toledo, Ohio, recently.

Charles Reuben McCreery, M.D., Tacoma, to Miss Bertha Frances Harris of Seattle, May 14.

Mortimer Elihu Embick, M.D., to Miss Katherine M. Scanlon, both of Chicago, at South Bend, Ind., May 17.

Craig Thomas Burns, M.D., Oklahoma City, Okla., to Miss Maud Staniland of Buffalo, N. Y., May 17.

George Cummings Albee, M.D., to Miss Mary Robinson West Reed, both of New York City, May 4.

William A. Hulbush, M.D., Philbrook, Mont., to Miss Bertha Isidora Elizabeth Krug of Fond du Lac, Wis., May 16.

John W. Kelly, M.D., to Miss Maude Josephine Wolfe, both of Springfield, Ill., May 7.

Deaths

Barton H. Potts, M.D. University of Pennsylvania, Philadelphia, 1891; a member of the American Medical Association, and American Otological Society and fellow of the College of Physicians of Philadelphia; resident physician to the Children's Hospital, Philadelphia, and Presbyterian Hospital, Philadelphia; laryngologist and aurist to St. Mary's Hospital; laryngologist to the Pennsylvania Training School for Feeble-Minded Children and aural surgeon to the dispensary of the Children's Hospital; laryngologist and aurist and chief of the nose and throat division of the German Hospital; died at his home in Philadelphia, May 8, from pneumonia, aged 41.

Alonzo Potter Neale Painter, M.D. Jefferson Medical College, 1890; a member of the Medical Society of the State of Pennsylvania, National Association of U. S. Pension Examining Surgeons; formerly president of the Armstrong County Medical Society, and physician of Armstrong county; staff physician to Kittanning General Hospital; secretary of the local pension board; died at his home in Kittanning, May 2, from the effects of a gunshot wound of the heart, self-inflicted, it is believed, with suicidal intent, while despondent on account of prolonged illness, aged 41.

George Henry Kenyon, M.D. University of Vermont, Burlington, 1866; a member of the American Medical Association and Association of Military Surgeons of the United States; surgeon of the United Train of Artillery for several years; made assistant surgeon-general of Rhode Island in 1883, and appointed surgeon-general of Rhode Island Militia with the rank of brigadier-general in 1894; treasurer of the local board of U. S. Pension Examiners; a veteran of the Civil War; died at his home in Providence, May 7, from nephritis, aged 65.

George Arnold Bellows, M.D. Detroit Medical College, 1881; a member of the American Medical Association; physician to the Seneca County (N. Y.) Almshouse from 1884 to 1892; health officer of Waterloo from 1882 to 1883; U. S. pension examining surgeon from 1887 to 1895; coroner of Seneca County for several years, and since 1891, a member and secretary of the board of trustees of Waterloo Academy; died at his home in Waterloo, May 10, from acute nephritis, aged 53.

Benjamin Alexander Cheek, M.D. University of Pennsylvania, Philadelphia, 1861; a member of the Medical Society of the State of North Carolina, and formerly president of the McDowell County Medical Society; surgeon of volunteers during the Civil War; died at his home in Marion in April, from nephritis, aged 72.

Peter J. McCourt, M.D. New York University, New York City, 1890; formerly a member of the American Medical Association; a member of the Medical Society of the State of New York, and a fellow of the New York Academy of Medicine; of New York City; a veteran, and crack shot of the Seventh Regiment, N. G. N. Y.; died at his home in Mount Vernon, N. Y., May 7, aged 68.

Henry Warren Fishel, M.D. University of Maryland, Baltimore, 1886; a member of the Medical Society of the State of Pennsylvania; formerly of Dillsburg; a member of the legislature from York county in 1894; ophthalmologist to the Messiah Home for the Children and Aged, Harrisburg; died at his home in that city, May 9, from cerebral hemorrhage, aged 58.

Jacob Imboden Leas, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1857; formerly surgeon of the Iowa Central Railroad at Neligh, Neb.; local surgeon and later general consulting physician and surgeon of the Fremont, Elkhorn and Missouri River Railroad at Chadron, Neb., and mayor of that city in 1891; died at his home, April 22, aged 75.

Richard Arthur DeKay, M.D. Bellevue Hospital Medical College, 1890; a member of the Medical Society of the State of New York; for several years health officer of the town of Rockland, and an inspector of the State Department of Health; was found dead in his office in Livingston Manor, May 3, from pulmonary edema following influenza, aged 46.

Emory Ellsworth Stover, M.D. State University of Iowa, Iowa City, 1898; a member of the Upper Des Moines, Iowa, and Southwestern Minnesota Medical societies; local surgeon of the Northwestern System, and health officer of Bigelow, Minn.; died recently at his home in that place from pulmonary tuberculosis, aged 45.

Tomlinson Fort Brewster, M.D. Jefferson Medical College, 1856; surgeon of the Fifty-fourth Georgia Regiment, C. S. A., during the Civil War; for several terms a member of the state legislature; superintendent of the Grady Hospital, Atlanta, for fourteen years; died in that institution, May 1, from nephritis, aged 76.

Walter S. Tingley, M.D. Medical College of Indiana, Indianapolis, 1884; for twelve years coroner of Campbell county, Ky.; formerly a resident and at one time health officer of Newport; pastor of the Christian Church of Harrisburg, Ind.; died in Speer's Memorial Hospital, Dayton, Ky., May 6, from nephritis, aged 63.

Wilson Lockhart, M.D. Jefferson Medical College, 1853; formerly superintendent of the Eastern Washington Hospital for the Insane, Medical Lake; at one time superintendent of the Indiana State Hospital for the Insane; died in his office in Seattle, April 28, from cerebral hemorrhage.

Paul Mundy St. Clair, M.D. Medico-Chirurgical College of Philadelphia, 1906; a member of the resident staff of Blockley Hospital, Philadelphia; for two years assistant physician in the Central Indiana Hospital for Insane, Indianapolis; died in Blockley Hospital, May 12, from meningitis, aged 27.

Lindsay Johnson, M.D. University of Louisville, 1874; Hospital College of Medicine, Louisville, 1877; a member of the Medical Association of Georgia; for several years professor of anatomy in the Hospital College of Medicine; died at his home in Cartersville, Ga., May 11, aged 58.

Ezra J. Ayers, M.D. Eclectic Medical College of Pennsylvania, Philadelphia, 1871; of California, Mich.; for more than 40 years a practitioner of California township, Kent county, Mich.; was injured in a runaway accident near his home, May 12, and died early next morning, aged 70.

Robert B. Wilson, M.D. Syracuse University, 1894; for 40 years a practitioner of Tower City, Pa., and publisher of the *Echo*; chief burgess and member of the school board of Tower City; died at the home of his son in Ardmore, May 8, from cerebral hemorrhage, aged 80.

Samuel Beach Jones, M.D. College of Physicians and Surgeons, New York City, 1872; a member of the Medical Society of the State of New York and the New York Academy of Medicine; died at his home in New York City, May 13, aged 67.

Landon C. Johnson, M.D. Ensworth Medical College, St. Joseph, Mo., 1893; formerly assistant health officer of St. Joseph, and superintendent of the Enworth Hospital; died at his home in Joplin, May 2, from cancer of the stomach, aged 43.

Isaiah B. Seagley, M.D. College of Physicians and Surgeons, Chicago, 1896; a member of the American Medical Association; formerly of Scotland, S. D.; died suddenly at his home in Presho, S. D., May 7, from angina pectoris, aged 47.

Charles Ward Thorpe, M.D. Gross Medical College, Denver, 1903; acting assistant surgeon in the U. S. Army with Philippine service; formerly of Denver; died at his old home in Nicholasville, Mich., April 16, aged 39.

Lucius S. Campbell, M.D. American Health College, Cincinnati, 1882; for many years a practitioner of Marshfield, Mo.; died at the home of his son in Springfield, Mo., April 11, from senile debility, aged 83.

Thomas Green Duncan, M.D. University of Louisville, 1868; Bellevue Hospital Medical College, 1870; a Confederate veteran; died at his home in Victoria, Texas, May 13, from cancer of the liver, aged 69.

James Thomas Polson (license, Mo., 1883); a member of the American Medical Association; for 44 years a practitioner of Laclede, Mo.; died at his home, April 13, from carcinoma of the thyroid gland, aged 71.

William D. Scott, M.D. Rush Medical College, 1866; a member of the Michigan State Medical Society and a veteran of the Civil War; died at his home in Ithaca, May 9, from cancer of the throat, aged 68.

Benjamin F. Budworth, M.D. University of Minnesota, Minneapolis, 1902; of Shelly, Minn.; died in the Northwestern Hospital, Minneapolis, May 9, from pneumonia, following pulmonary abscess, aged 41.

John Eliot Blaine, M.D. Bellevue Medical College, 1872; in charge of an institution for the cure of alcoholism and the drug habit in St. Louis; died in the institution, May 11, from angina pectoris, aged 59.

Isaac Carey, M.D. Botanico-Medical College, Cincinnati; for more than sixty years a practitioner of Grant county, Ind.; died at the home of his son in Marion, Aug. 2, 1909, from senile debility, aged 96.

William Clark Snyder, M.D. New York Homeopathic Medical College, New York City, 1906; of Utica, N. Y.; died at the home of his father in Binghamton, N. Y., April 30, from tuberculosis, aged 28.

Martin Cagle, M.D. Georgia College of Eclectic Medicine and Surgery, Atlanta, 1894; of Adairsville, Ga.; was crushed between a grain platform and a moving boxcar at Atlanta, May 6, and instantly killed.

Russell B. Moore, M.D. Kansas City (Mo.) Hospital College of Medicine, 1885; for 51 years a practitioner of Auburn, Ga.; died at his home in that city, March 18, from intestinal obstruction, aged 76.

William P. LaFollette, M.D. University of Louisville, 1880; formerly of New Salisbury, Ind.; died at his home in Mott, Harrison county, Ind., recently, from pulmonary tuberculosis, aged 58.

Jenkins DeVaney Pope, M.D. St. Louis Medical College, 1851; formerly a member of the Arkansas Medical Society; died at the home of his son in Monticello, May 1, from senile debility, aged 85.

Thomas Hall McCorkle, M.D. Medical College of Ohio, Cincinnati, 1879; of Terre Haute, Ind.; died in St. Anthony's Hospital, Terre Haute, March 29, from nephritis, aged 64.

Robert L. Duncanson, M.D. Ensworth Medical College, St. Joseph, Mo., 1892; of Ionia, Kan.; died at the home of his daughter in that city, April 25, 1909, from tuberculosis.

Patrick H. Perkins, M.D. McDowell Medical College, St. Louis, 1855; for 45 years a practitioner of Linneus, Mo.; died at his home, April 14, from senile debility, aged 81.

Lewis A. Denton, M.D. Long Island College Hospital, Brooklyn, 1876; a member of the Buffalo Academy of Medicine; died at his home, May 8, from pneumonia, aged 60.

Hezekiah Doster, M.D. Bellevue Hospital Medical College, 1872; of Poneto, Ind.; died at the home of his daughter in that place, May 11, from paralysis, aged 67.

Edward Franklin Bittner, M.D. Eclectic Medical Institute, Cincinnati, 1899; died suddenly at his home in Somerset, Pa., April 29, from angina pectoris, aged 41.

Simon P. Putt, M.D. Starling Medical College, Columbus, Ohio, 1878; died at his home in Baltic, Ohio, May 1, from chronic interstitial nephritis, aged 56.

Robert Franklin Conkle, M.D. Western Reserve University, Cleveland, 1872; died at his home in Coraopolis, Pa., May 8, after a surgical operation, aged 61.

Hiram Lee Nease, M.D. Vanderbilt University, Nashville, 1898; died at his home in Shelbyville, Tenn., May 9, from cerebral hemorrhage, aged 43.

George W. Wilson, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1863; died at his home in Curtis, Neb., May 5, from senile debility, aged 75.

Irvin J. Bowen (examination, N. Y., 1874); a practitioner for 51 years; died at his home in Ashville, N. Y., May 12, from heart disease, aged 76.

Sandapher B. Spickard, M.D. Vanderbilt University, Nashville, 1882; died at his home in Jackson, Miss., May 7, from cerebral hemorrhage, aged 53.

Van Wagener, M.D. Medical College of Ohio, Cincinnati, 1876; died at his home in Bridgeport, Ohio, May 6, from cerebral hemorrhage, aged 56.

Philip Lloyd Pollock, M.D. Hahnemann Medical College, Philadelphia, 1901; of Fort Worth, Texas; died in a hospital in that city, May 1, aged 30.

Charles Treat Lyons, M.D. New York University, New York City, 1852; died at his home in Waverly, N. Y., May 9, from senile debility, aged 88.

Robert H. Harmon, M.D. Tulane University, New Orleans; a Confederate veteran; died at his home in Marion Station, Miss., April 30, aged 66.

Horace B. Duncan, M.D. University of Louisville, 1876; of Williamsburg, Ky.; died in the University Hospital, Louisville, May 2, aged 72.

Joseph Brackbill, M.D. University of Pennsylvania, Philadelphia, 1869; died at his home in Reading, May 6, from heart disease, aged 65.

Delma C. Campbell (license, Miss., 1901); formerly of Hesterville, Miss.; died recently in Chihuahua, Mexico, from tuberculosis, aged 34.

Walter C. Jackson, M.D. Tulane University, New Orleans, 1900; died at his home in New Orleans, May 11, from appendicitis, aged 30.

Buchanan Ramer, M.D. Indiana Eclectic Medical College, 1890; died at his home in Surprise, Ind., May 8, from nephritis, aged 53.

Society Proceedings

COMING MEETINGS

AMERICAN MEDICAL ASSOCIATION, ST. LOUIS, June 7-10.

American Academy of Medicine, St. Louis, June 4-6.
American Assn. of Medical Milk Commissions, St. Louis, June 6.
American Association of Medical Examiners, St. Louis, June 5-6.
American Gastro-Enterological Association, St. Louis, June 6-7.
American Proctologic Society, St. Louis, June 6.
American Society of Tropical Medicine, St. Louis, June 11.
American Urological Society, St. Louis, June 6-7.
Assn. of Amer. Teachers of Diseases of Children, St. Louis, June 6.
Maine Medical Association, Bar Harbor, June 29-30.
Massachusetts Medical Society, Boston, June 7-8.
Nat. Con. State Med. Exam. and Licensing Bds., St. Louis, June 6.
New Jersey Medical Society, Atlantic City, June 28-30.

Rhode Island Medical Society, Providence, May 31.
Wisconsin, State Medical Soc. of, Milwaukee, June 22-24.

ASSOCIATION OF AMERICAN PHYSICIANS

Twenty-fifth Annual Meeting, held at Washington, D. C., May 3-5, 1910

The President, Dr. Henry Hun, of Albany, in the Chair

Officers Elected

The following officers were elected: President, Dr. F. Forchheimer, Cincinnati; vice-president, Dr. J. George Adami, Montreal; secretary, Dr. George M. Kober, Washington (reelected); recorder, Dr. S. Solis Cohen, Philadelphia (reelected); treasurer, Dr. J. P. Crozer Griffith, Philadelphia (reelected); member of council, Dr. George Dock, New Orleans.

Etiology of Subacute Infective Endocarditis

Dr. E. Libman and Dr. H. L. Celler, New York: During the past eight years we have studied 43 cases of subacute infective endocarditis, in 36 of which blood cultures were made during life. The cases varied in duration from four months to a year and a half, and in nearly all the onset was insidious. Fever occurred in all. Other frequent symptoms were sweats, malaise and gastric or intestinal disturbances. There were progressive weakness and emaciation, and the spleen was nearly always enlarged and palpable. There were pains in the joints, bones and muscles. Painful erythematous cutaneous nodules appeared to be pathognomonic. No patient recovered. Except for one case of infection by the influenza bacillus, there have been found in the blood of these cases two types of organisms, the one resembling the other quite closely. These organisms resemble the pneumococcus in certain respects, but most of them more closely resemble the streptococcus. These organisms, when found in the blood, seem to be diagnostic of the disease.

DISCUSSION

Dr. Francis P. Kinnicutt, New York: As I understand Dr. Libman, the prognosis in these cases depends largely on the results of the blood culture. If this disease can be proved to be infectious and due to the organism he describes, the prognosis must be extremely unfavorable. If we can determine the prognosis by means of blood cultures, that should be a useful means at our disposal.

Dr. James B. Herrick, Chicago: I would like to ask Dr. Libman in what proportion of cases was there a history of valvular lesions preceding the chronic endocarditis? Also, what relation does the organism he described bear to the so-called organism of rheumatism?

Dr. Frank Billings, Chicago: My experience with cases of chronic infective endocarditis agrees with that of Dr. Libman in regard to the clinical course of the disease and the fatality of it. Last year we reported 15 cases of this type, and since that time we have had 10 or more. One finds the disease more prevalent than is commonly supposed. The disease may be mistaken for malaria, subacute rheumatism, typhoid or tuberculosis. I do not think one can make a diagnosis of the condition by taking blood cultures. One may say that he has a case of chronic infective endocarditis to deal with, but one must remember that some of the very important diagnostic symptoms are absent at the beginning of the disease. The blood cultures will certainly help us in determining the various forms of endocarditis.

Dr. E. C. Rosenow, Chicago: I am sure we are dealing with the same disease, although in our studies to differentiate the organisms we differ slightly in the smaller details. During the first year of this work I thought I was dealing with the *Streptococcus pyogenes*. Further studies, however, during the last two years have convinced me that I was dealing, not with the streptococcus, but really with a modified pneumococcus.

Dr. F. Forchheimer, Cincinnati: It seems to me the most important outcome of this discussion is the fact that one observer here has isolated a pathogenic organism and another observer has verified his findings in a disease which we have been taught to believe was due to a number of different organisms. If this is correct, then we have made an enormous step forward in the recognition of this disease. I have seen a large number of cases which clinically would be considered under the head of this form of endocarditis. I have had a number of cultures made, and I have found a large number of organisms. Some of my patients have recovered. Evidently we are dealing with a different form of endocarditis.

Dr. Libman: One should expect a fatal termination in every case in which he finds this organism in the blood. In all the cases that I have had the disease has been superimposed on previous cardiac disease. As to the relationship of the organism to the so-called organism causing rheumatism, I cannot answer, as no bacteria have been found in the blood in the latter condition. As to the question of other means of diagnosis, we have made studies of the blood microscopically with the hope of finding certain cocci, but we have been unsuccessful. When these organisms were not found in cultures, they were not found otherwise.

The Commoner Types of Functional Cardiac Murmurs

Dr. William S. Thayer, Baltimore: During the past seven years I have been especially interested in studying cardiac murmurs in individuals who appeared to be perfectly normal. A cardiac murmur is but one and sometimes an unimportant one of the links in the chain of evidence leading to the recognition of disease of the heart. Certain cardiac murmurs are present normally in a large proportion of healthy young people. The common forms of these murmurs are: (a) The basic systolic murmur, heard best in the third left interspace, and often all over the area in the recumbent posture. This murmur disappears in the erect posture or full respiration. (b) The systolic murmur, sometimes limited to the apex, sometimes heard all over the cardiac area in the recumbent posture, disappearing in the erect posture. (c) The cardiac respiratory inspiratory murmurs. The commoner functional murmurs, those heard in healthy individuals, should be carefully distinguished from those other murmurs which may arise at various orifices, without actual valvular disease, but, nevertheless, as a result of pathologic changes in the heart muscle or in the blood. The anemic murmurs, systolic and diastolic, depend on the weakness of the heart muscle. A familiarity with the cardiac murmurs common in the normal individual is at least as important as an acquaintance with those murmurs which are associated with cardiac disease.

Epidemiology of Poliomyelitis

Dr. Joseph Collins, New York, read a paper which will appear in The Journal.

Pathology of Poliomyelitis

Dr. B. Sachs, New York: The examination of pathologic specimens from cases of acute poliomyelitis bears out the toxic character of the disease process. It is vascular in origin, not confined solely to the area of the anterior spinal artery, as was once believed, but involves the central gray matter and almost the entire cross-section of the cord; at times it involves the lower portions of the brain axis. The disease expends its force chiefly on the ganglion cells of the anterior horns, so that there is still much justification for retaining the old name, poliomyelitis anterior.

DISCUSSION

Dr. M. H. Richardson, Boston: The State Board of Health of Massachusetts began an investigation of this disease three years ago. In 1907 there were 235 cases; in 1908, 185; in 1909 the cases numbered nearly 1,000. That is not essentially a city disease, but rather a rural or suburban disease. Any community which has a severe epidemic one year does not necessarily have a severe one the next. The seasonal incidence of this disease is interesting. In this climate the disease occurs between the months of May and November; in the southern hemisphere it prevails from March to May. In writing to the medical officers in the southern cities and in Cuba a curious fact came out, namely, that the disease in Cuba also had a seasonal incidence from May to October. This shows that temperature alone cannot account for the incidence. We wrote to several institutions in the state in which children are kept, and another curious fact came out, namely, that among 3,600 children in these institutions in the state only one case was found in a child under fifteen years of age. This is interesting in proving that children living in these institutions and protected from those who have the disease do not get it.

A circular letter was sent to physicians in the state recommending that the cases be quarantined and that hexamethylenamin be administered. In every case that came to autopsy in Massachusetts there seemed to be a definite relation between the fatal cases and an enlarged thymus gland. I should like to ask if that is a common experience with others here who have studied the disease.

Dr. B. Sachs: In performing autopsies on these cases other organs besides the thymus gland will yield evidence of a general infection. In the lungs frequently will be found a bronchopneumonia. The liver and the spleen will show distinct evidences of a general infection. In one case I saw every gland in the body was found to be enlarged.

Congenital Syphilis of the Heart

Dr. A. S. Warthin, Ann Arbor: I wish to call attention to the diffuse fibrosis of the myocardium due to congenital syphilis and the relation of the congenital fibrosis of the heart to cardiac insufficiency in young and early life. Cardiac changes occur in all cases of congenital syphilis in which the liver shows the changes characteristic of congenital syphilis. Infantilism and delayed puberty are associated with this form of heart lesion.

(To be continued)

ILLINOIS STATE MEDICAL SOCIETY

Sixtieth Annual Meeting, held at Danville, May 17-19, 1910

The President, Dr. J. L. Wiggins, East St. Louis, in the Chair

Addresses of welcome were delivered by Hon. Louis Platt, mayor of Danville, and by Dr. Benjamin Gleeson, president of the Vermillion County Medical Society. President Wiggins responded to these addresses.

The New Officers

The following officers were elected for the ensuing year: President, Dr. Alfred C. Cotton, Chicago; president-elect, Dr. W. K. Newcomb, Champaign; vice-presidents, Drs. J. W. Hamilton, Mount Vernon, and J. E. Stubbs, Chicago; treasurer, Dr. E. J. Brown, Decatur, reelected; secretary, Dr. E. W. Weis, Ottawa, reelected; delegates to the American Medical Association, Drs. W. F. Grinstead, Cairo; E. W. Weis, Ottawa; S. C. Glidden, Danville; J. E. Allaben, Rockford; J. L. Wiggins, East St. Louis; Albert L. Brittin, Athens; alternates, Drs. G. W. Green, Chicago; George F. Allen, Aurora; W. E. Shallenberger, Canton; George F. Butler, Chicago; Frederick A. Tice, Chicago, and M. S. Marcy, Peoria.

Aurora was selected as the place for holding the next annual meeting.

Medical Treatment of Pelvic Diseases of Women from the Standpoint of the Surgeon

Dr. J. F. Percy, Galesburg: My conception of a medical pelvic case is one in which there is infection, misplacement and distress without fixation. Fixation is Nature's slow way of improving local conditions in the pelvis until either the menopause or surgery removes the conditions which make the fixation necessary. Surgery has won some of its greatest triumphs in the cases where inflammatory fixation was substituted for surgical fixation. Surgery has done some of its worst work or gotten almost negative results in cases of infection. On the other hand, the medical practitioner, in attempting to treat cases, has converted many of them into major surgical cases. The average pelvic case complains more of backache than of any other symptom. There are other adjuncts to the successful treatment of this class of patients than mechanical or medical procedure. The two most important are physical and sexual rest, and second, freedom from worry.

DISCUSSION

Dr. Clifford U. Collins, Peoria: I have very little faith in the local treatment of pelvic diseases. I have held to the views advanced by Dr. T. J. Watkins, who, in 1905, called attention to the inefficacy of vaginal douches and iodin applied to the vaginal vault and tampons put in the vagina for the treatment of inflammation of organs high up in the pelvis, and which have an entirely different blood supply. Such treatments may do good for a time, but the relief is not permanent. I find it advantageous in these cases to call to my aid the internist either before or after operation.

Dr. S. C. Stremmel, Macomb: I want to emphasize rest in the pelvic infections of women. I know of no form of local treatment which does any good in the treatment of these pelvic infections in women. Rest is the best form of treatment for inflammation or infection anywhere, and where it can be possibly secured it may alone do the work.

Dr. Edward Bowe, Jacksonville: In the majority of women who have become neurasthenic from injuries in labor, or in whom a pathologic condition has existed for some time, the neurasthenia has become fixed, and local treatments will only exaggerate the condition and create a degree of introspection bordering on psychasthenia. The best treatment is rest.

Dr. W. F. Grinstead, Cairo: Both the physician and the surgeon are apt to go to extremes and see everything from their particular standpoint. The physician gets in his good work in these cases in the acute stage. He tries to effect a cure before the condition becomes surgical, because in the beginning most of these conditions are medical. When we have an infection that has gone on to the chronic stage, which involves the cervix, or has extended into the corpus or into the tubes, the physician is wasting his time as well as the means of the patient in attempting to restore that patient to health by the usual medical means. We have then a condition which must be relieved surgically.

Dr. Channing W. Barrett, Chicago: The question is one of close study of the pathology of pelvic disease. A patient with pelvic disease is not going to be cured purely by rest, because there are a number of conditions which will not be affected by the rest treatment. The rest treatment is an aid. Pelvic disease is not going to be cured altogether by operative measures because there are a lot of conditions which surgery would not help but injure.

Dr. M. S. Marcy, Peoria: Dr. Percy in his paper made the statement that the physician who treats these patients by local means is imposing on them. I would like to ask him if the physician imposes on a patient when he can by local treatment relieve a backache, a severe pain on the top of the head, etc.

Dr. J. F. Percy: In reply to the remarks of Dr. Marcy, the point I tried to make was with reference to the value of fixation. We should simply follow Nature's methods. Nature fixes these structures for two purposes; first, to get a chance at the infection, and second, to hold the parts as nearly in the anatomic positions as they were when the infection began.

Two Thousand Blood Examinations for Hemameba of Malaria

Dr. T. M. Aderhold, Zeigler: To avoid errors, accept nothing but the microscopic diagnosis. Anything which lowers the vitality of the individual, whether fatigue, heat, cold, or other disease, predisposes him to malarial infection, or to a relax if he already harbors the parasite. In the locality where these observations took place malaria was not as prevalent either as a primary disease or complicating other diseases, as it was thought to be by the profession of the locality. If a person has more than one attack of malaria within a year, the attacks after the first one are more liable to the relapses than reinfections. *All malarial patients should be advised to take three months' treatment. Malaria complicating other diseases should be treated as though no other disease were present until the acute symptoms subside, and then the treatment should be modified. A promise of cure in malaria should not be given until the patient has been more than one year without symptoms.*

Some Diabetic Obiter Dicta

Dr. S. T. Robinson, Edwardsville: We should bear these diabetic facts in mind: While at the beginning of treatment there is intolerance of carbohydrate, so an abrupt and radical reversal of diet may produce intolerance also of proteid. Thus there will be a double intolerance and the trouble deepens. But it is wholly on the establishment of a tolerance of proteid that success depends; *for it is only after a more or less severe proteid diet that tolerance of carbohydrate will be regained. Once this has been accomplished, the urine may begin to run* sugar-free. If now, with tolerance of such a diet fully established, some weight is gained, he has made a distinct stride forward. Even more notable, if with the same diet, and a urine continuously sugar-free, there is secondarily some loss of flesh, he has made much greater progress, for it will be found that he can again assimilate an appreciable quantity of carbohydrate. Such results are, however, seldom obtained by simply directing the patient to avoid sugar and starch, and to live mostly on meat, or by handing him a printed diet list. To-day a technic in this matter has developed that calls for much special training. The surgeon exacts a well-appointed hospital for his operations, so the physician, who must guide and educate the diabetic through a maze of chemical, physiological and dietetic technic, will demand and receive the same helps.

The Technic and Value of the Wassermann Test in the Diagnosis and Treatment of Syphilis

Dr. W. T. Mefford, Chicago: The technic is so simplified that all physicians can mix the materials and define the results. By the test one is enabled to diagnose active syphilis in all stages, to know whether treatment is being carried on successfully, and how long it should be continued, or when to begin treatment in late syphilis. Its greatest value is to the internist, enabling him to differentiate many conditions presenting complicated clinical symptoms. *Active syphilis is often present with many chronic or long drawn-out diseases, as tuberculosis, diseases of the liver, typhoid fever and artery diseases, etc.*

DISCUSSION

Dr. F. G. Harris, Chicago: The technic of this reaction is difficult and all the attempts made to modify it with a view to simplifying it have simply created confusion and have brought the Wassermann test in this country into more or less disrepute. *The technic of mixing solutions and determining whether one hemolyses or one does not is simple. When we get a tube that hemolyses it may show negative, while if we let another man make the test it may show positive. I am opposed to the drop method of doing a Wassermann. We know that this is a quantitative reaction, and where we are working in drops we are working with unknown quantities.*

Dr. Robert H. Babcock, Chicago: The value and necessity of the Wassermann test in ordinary clinical practice have been borne out by my experience this winter. Of a number of cases thus tested, one was a combined pulmonary tuberculosis with aortic insufficiency, the man having attacks of hemoptysis. Suspecting there might be a syphilitic basis, I had the test made, and the reaction was positive. He was put on mercury and his physician reported within three weeks marked improvement, with cessation of the hemoptysis.

Bacteriology and Pathology of Joint Infections

Dr. E. E. Irons, Chicago: In addition to infections of the joints resulting from trauma or direct extension from an adjacent focus of suppuration, or associated with certain specific diseases, such as syphilis and tuberculosis, lesions of the joints, periosteum and tendon sheaths may occur in practically all the acute infectious diseases, either as an incident in the course of the disease, or as a more or less remote sequel. The pathologic changes in the joint depend on the extent of involvement of the articular and periarticular tissues, the duration of the active stage of the infection, and the relative virulence of the infecting agent.

OHIO STATE MEDICAL ASSOCIATION

Sixty-fifth Annual Meeting, held at Toledo, May 11-13, 1910

The President, Dr. W. H. Snyder, Toledo, in the Chair

The officers elected were named in The Journal, May 21, page 1700.

Causes and Operative Treatment of Sterility in the Male

Dr. Francis R. Hagner, Washington, D. C.: Sterility in the male is due, first to aspermia; second, to azoospermia; third, to oligospermia; fourth, to anatomic abnormalities which prevent the passage of semen through the urethra; fifth, to stricture of the urethra. Men with double undescended testicles are almost invariably sterile; and also those whose testicles have received serious injury, causing destruction of the secreting structures or occlusion of the efferent ducts. This later is a condition which obtains in epididymitis, the inflammatory exudate and presence of abscesses in the epididymis, with the consequent formation of scar tissue cause an occlusion of the efferent ducts of the epididymis. Abscess formation in acute gonorrheal epididymitis is much more common than is generally supposed, as in 48 cases that I have operated, abscesses were demonstrated in 80 per cent. Frequent masturbation and sexual excesses, syphilis and tuberculosis, are frequent causes of sterility. Another cause is the *x*-ray. The principal cause of sterility in the male, however, is bilateral gonorrheal epididymitis. In this disease the globus minor is the portion of the epididymis most involved, and it is in this portion that occlusion has the most dangerous results, as there is but one efferent duct, while in the globus major the efferent ducts are numerous, and the obstruction of one or two would still leave other channels. Dr. Quinby of Boston has tied off the vas deferens in guinea-pigs at its exit from the globus minor, and then made an anastomosis between the globus major and the vas above the ligation, in the method recommended by Martin of Philadelphia. In from 10 to 27 days, 3 out of 4 pigs thus operated on showed spermatozoa in the fluid ejaculated by means of electric stimulation. In dogs spermatozoa reappear in from 6 to 8 days.

Anastomosis of the vas deferens is performed by making an incision through the skin and coverings of the epididymis, which is approached from the outer side so as not to wound the spermatic artery. The artery of the vas is pushed aside and a one-half inch incision is made in the vas deferens on a level with the globus major, along its axis, care being taken to get into the lumen of the tube. A portion of the globus major is picked up between two fine forceps and an elliptical piece removed to correspond with the incision in the vas deferens. Four sutures are inserted by curved intestinal needles, one at the upper angle of the wound joining the vas and the cut surface of the epididymis, one at the lower angle, one at the outer and one at the inner side. When these are approximated, a perfect little pocket is formed by the spreading out of the cut vas deferens and the elliptically cut globus major. The wound is then closed and dressed.

Features in the Surgical Treatment of Gastric Ulcer

Dr. M. D. Haines, Cincinnati: The stomach, duodenum, pancreas and liver are intimately related embryologically, anatomically and physiologically, and it may be concluded, therefore, that they are intimately associated pathologically, and that a serious lesion, such as chronic gastric ulcer, will necessarily influence in a greater or lesser degree the functions of the pancreas and liver. Kaufman showed that chronic cholecystitis with acute exacerbations always has a direct influence on ulcer; conversely, alterations in stomach secretions cause acute exacerbation in cases of chronic cholecystitis. It is a well-known fact that mental conditions influence the bodily secretions in general, examples being the influence of the pregnant uterus on the stomach, and Opie's well-known explanation of pancreatitis. It may be concluded, therefore, that the stomach in its secretory functions is no exception to the general physiologic laws, regulating the secretion of organs in general. In view of these facts, in a number of instances I have drained the gall-bladder in conjunction with operative procedures instituted for the relief of chronic ulcer of the stomach. My patients have done better after operation than when a mere gastrojejunostomy or other operative procedure had been done on the stomach for the relief of ulcer.

DISCUSSION

Dr. R. B. Hall, Cincinnati: I have some knowledge of Dr. Haines' work in adopting this method of treatment, and his patients recovered better than when drainage was not used. I have drained the gall-bladder in a few instances, and the patient makes an easier and smoother convalescence.

Dr. Means, Columbus: I can recall some cases in which there might have been some relief to my patient had I drained the gall-bladder. For instance, in the last six months I did a gastrojejunostomy, and the patient within 24 hours from the operation began retching and vomiting bilious matter, and eventually died. It is barely possible that had drainage of the gall-bladder accompanied the operation, the patient might have been relieved, and yet I am not clear as to the theory.

AMERICAN THERAPEUTIC SOCIETY

Eleventh Annual Meeting, held at Washington, D. C., May 5-7, 1910

Election of Officers

Dr. Harvey W. Wiley, Washington, D. C., was elected president. The following were reelected: Drs. A. D. Blackader, Montreal, Howard van Rensslaer, Albany, N. Y., and Robert T. Morris, New York, vice-presidents; Dr. Noble P. Barnes, Washington, D. C., secretary; Dr. A. Ernest Gallant, New York, treasurer, and Dr. P. B. Porter, New York, editor of the transactions. The next place of meeting is to be Boston, in May, 1911.

President's Address: The Progress of Therapeutics

Dr. James C. Wilson, Philadelphia: At the beginning of the last third of the nineteenth century the study of causes formed a sure foundation in the facts of science, and empiricism in therapeutics gave way to rationalism. Half a century has not yet elapsed, and the art of healing shows signs of being revolutionized. The modern theories of infection and immunity are established on unassailable facts. The history of the advance of medicine would be but a series of disconnected episodes were it not that it teaches us that here, as in other fields of human endeavor, knowledge ripens slowly, and that failures are the stepping-stones to success. It teaches us another lesson worth the knowing, namely, that the control of efforts can be compassed only through a knowledge of their causes. More than two thousand years of empiricism before reason came to her own in medicine! There were charms and incantations and pilgrimages and votive offerings, but no calamity of plague or pestilence was averted, and no man who was really sick was made well. Drugs there were of all kinds, and many of them potent, but "Not poppies nor mandragora; nor all the drowsy syrups of the East" could touch the ills of mankind at their source. Jenner alone in all time before the era of bacteriology—our era—applied the knowledge of causes to preventive medicine and wrought the wonder of a rescued world. To-day we watch the effects of the antitoxin made possible by the work of Klebs and Loeffler, or those which follow the administration of Flexner's serum, and experience the sensation of having witnessed a miracle. In later times there has been less and less of indirection and a progressively increasing tendency toward practical results. Specialism and organization are complemental. Without the one the other cannot exist, and the new medicine is the product of this union. A comprehensive survey of the work done by the members of this society individually and collectively discovers here also a well-defined tendency to specialism. Three main therapeutic trends have been differentiated: First, the Hippocratic medicine, in which the forces of Nature other than drugs play the most important rôle; second, the subject of psychotherapy and re-education in the management of some of the functional neuroses; third, the general study of therapeutics as comprising the empiric use of drugs, on the one hand, and the rational employment of causal remedies on the other. Our work consists in the application of the means to the end, and the time is now at hand for us to enter on the latest phase of applied therapeutics from this point of view, namely, rational therapeutics based on the latest results of the scientific study of the causes of disease, serum therapy, opotherapy, and the use of bacterin.

The Treatment of Pneumonia

Dr. Alexander McPhedran, Toronto: It is incorrect to call pneumonia a fever, as is now often done. The disease is only one phase of pneumococcic infection, and in it there is a local, as well as a general infection. Death almost always occurs through the vascular system, the vessels, as well as the heart, being affected; and is due to the depression of the circulatory center in the medulla caused by the toxic albuminoid of the pneumococcus of cardiac failure. There are two groups of cases, the asphyxial and the syncopal. In the first, which is much the more common form, the venous system is surcharged with blood and the arterial undercharged. In the second, all the organs, including the heart, are anemic. In these cases, too, the right ventricle may be found distended, but this probably occurs only in the throes of death. In both classes of cases the aim of treatment is to raise the blood-pressure. There is no specific for pneumonia, and our ability to treat it has not kept pace with our knowledge of the features of the disease. The mortality is extremely high among urban populations, and I have observed that this is especially the case in two cities, Chicago and New York. The two most important causes of this appear to be the excessive heat in the houses and the lack of proper clothing for protecting the body. As regards the matter of prophylaxis, two diseases are particularly productive of pneumonia, measles and influenza, and very careful after-treatment in these would seem to have considerable effect in warding it off. The so-called curative treatment by means of a vaccine or serum has not as yet proved very satisfactory. If a cure is to be effected the agent of this character employed must be a bacterin rather than an antitoxin. A most serious difficulty in this kind of treatment is that there are various strains of pneumococci, and to have it efficient we should know the particular strain that is present in any given case, and then have a bacterin especially adapted for that form. At present, therefore, we have to rely on symptomatic treatment, or, as we had better call it, treatment of the patient. The usual essentials are complete rest, good nourishment, and plenty of fresh, cold air. On the whole, the latter is better than anything else as an element of success. In my experience the results are better in hospital than in private practice, because in hospitals the patient is under the constant supervision of a trained physician. I think too little opium is given in this disease. There is no cardiac tonic equal to opium and its derivatives, and in some cases no remedy but this will produce the desired effect. The cases in which opium is dangerous are not those of pure pneumonia, but rather bronchopneumonia. In the cases in which venesection is indicated this must be early and free in order to be effective.

Malarial Infections in the Canal Zone

Dr. F. N. Shook, U. S. N.: In this region the most important malarial infection, from the standpoint of diagnosis and prognosis, is the estivo-autumnal. Single tertian and double tertian infections are common, but quartan very rare. The principal types of estivoautumnal infections may be classified as (1) mild; (2) severe; (3) mixed; (4) pernicious, including the hyperpyretic type. The experience of physicians on the Isthmus emphasizes the following points: (1) In tropical malaria quinin should be given either in solution or capsules, as tablets may not be absorbed; (2) if properly administered, hypodermics of quinin rarely cause abscess; (3) in cases of malarial fever in adults in the tropics which do not show pernicious symptoms the treatment with an initial dose of twenty grains of quinin, preferably in solution, followed by ten grains three times a day, is almost uniformly successful; (4) in the treatment of malarial fever in pregnant women in the tropics the safest rule is to disregard the pregnancy and treat the malaria in the usual manner; (5) after surgical operations in malarial districts in the tropics pernicious malarial fever may develop unless a prophylactic course of quinin is first given.

Important Therapeutic Indications in the Treatment of Typhoid Fever

Dr. J. Blake White, New York: To the extent that we succeed in modifying the intestinal morbific process will we not only lessen the thermic changes attending the disease, but also prevent the various complications formerly so often encountered. As the fever apparently has its origin in the intestinal inflammation, and the absorption of specific toxins, the first therapeutic indication is in the direction of the use of remedies which have the essential quality of modifying this condition. No disease, in my opinion, is more manageable than typhoid fever, and I have yet to note as prompt or more constant effects from any kind of treatment in any other affection than those resulting from intestinal antiseptics in typhoid. As soon as the diagnosis is made, or earlier if there is any doubt about the matter, the combination used by Woodbridge should be given, though in somewhat larger doses than he recommended. The best manner of administering the remedies is in tablet triturates, each tablet to be followed by two or three swallows of some pure spring water, not aerated. After some modification of the fever is observed larger doses of the antiseptic may be given in capsules. Should the case not be seen until the patient has become delirious and internal medication is impracticable, I give sodium sulphoborate hypodermatically, and subsequently begin the internal antiseptic treatment as soon as the patient's condition permits. At an early stage, about the end of the second week, when, with rare exceptions, the temperature declines under the antiseptic treatment to normal, I usually give some alcoholic stimulant, as well as strychnin, in order to anticipate the debility likely to ensue after such fall. The practice of cold tubbing cannot be too strongly condemned, as it is too exhausting to the patient, and is also irrational, since this method of reducing the temperature is not intended to have, and never can have, any effect on the pathological causes of the hyperpyrexia. The simple temporary reduction of temperature has little advantage, and for the toxemia from local lesions and the general blood dyscrasia we have no better resource than antiseptic medication, the result of which is a permanent reduction of the fever. I am willing to admit, however, that ablutions have some useful application in strengthening the vital powers, and therefore approve of and practice regular lavations with sterile water and alcohol, the water being tempered to the enduring capacity of the patient. It is of vital importance that regular function of the bowels should be kept up throughout the illness and convalescence, and under the antiseptic method laxatives or rectal irrigation are not infrequently called for. The maintenance of the nutrition is, of course, of the utmost importance, and as to the dietary, eggs, milk and light meat broths may be given. I permit cereals, well boiled, at any time, and the resort to solid food just as soon as the patient's condition warrants it; generally at the end of the second week. In the management of typhoid much depends naturally on the ability, vigilance and devotion of the nurse.

The Treatment of Leukemia by the Roentgen Ray

Dr. Reynold Webb Wilcox, New York: The case here reported had apparently lasted about ten years when first observed on Sept. 4, 1909. The patient was a male, 29 years old. The pallor of the skin and mucous membranes were profound, and the spleen, which was hard, occupied the whole of the left abdominal cavity, extending two fingers' breadth to the right of the umbilicus. There was no tenderness over the flat bones, and no enlarged glands were felt. In the use of the *x*-ray, under the direction of Dr. Carl Beck, a hard tube was employed, with fifteen minutes' exposure over the spleen, two or three times a week. Iron and arsenic were also given.

Blood counts made from time to time showed, for the most part, a progressive improvement in the condition of the blood, and on April 28, 1910, the lower border of the spleen was but two finger breadths' below the free border of the ribs. The pallor had largely disappeared, and for the preceding two weeks the patient had engaged in active employment. In this instance the massive enlargement of the spleen, taken in connection with the absence of tenderness over any of the bones, and of any enlargement of the lymphatic glands, would indicate that this particular leukemia was of the splenic type, or possibly of the splenomedullary form sometimes called myelogenous. In this variety the Roentgen ray appears to be more successful than any other mode of treatment, though iron and arsenic are still believed to be of some service.

High Frequency Currents in the Treatment of Arteriosclerosis

DR. THOMAS E. SATTERTHWAITE, New York: Unless one has a static machine, a high frequency coil is best adapted for this kind of treatment. The powerful waves of the static form of electricity cause short waves of vibration in the capillaries, promote metabolism in an extraordinary way, and do no harm. In my experience, a diminution in the arterial pressure is the regular sequel to the use of the high frequency current, but the seances should not be prolonged beyond the time at which the pressure falls to normal. I have found that while the pressure may not always be reduced at each sitting, there was in all instances a progressive decline under the treatment. This should be given two or three times a week, or until the blood-pressure has fallen to the normal or nearly to it. It has sometimes been advised to use the faradic current as an adjuvant. Intestinal atony is often a complication of arteriosclerosis, and this current, applied over the abdominal walls, may be very helpful in relieving the constipation. In addition, mercurials, iodids, iron and arsenic should be employed according to the indications which may be present in any given case.

The Further Study of Diabetes as an Infectious Disease

DR. ALFRED KING, Portland, Me.: At the last meeting of this society I expressed the opinion that diabetes mellitus is an infectious disease, due to the presence of the yeast fungus, *Saccharomyces cerevisiæ*, and though, during the year that has since elapsed I have not had the opportunity to experiment on animals or complete my investigations, yet, with considerable additional experience, I have found nothing to disturb my confidence in the theory or my faith that it will be established. I have now examined forty patients and have obtained a pure fungus from the blood of all but one of these.

The Range of Activity and the Untoward Effects of Certain Spinal Analgesics, Based on Two Thousand Administrations

DR. W. B. BABCOCK, Philadelphia: The two thousand cases included all kinds of operations in all parts of the body. The safety of spinal, or, more properly speaking, nerve-root, anesthesia depends largely on the height in the spine of the nerve-roots which it is necessary to narcotize for any given operation. The higher up they are, the greater the danger. The delicate thing is to have the solution sufficiently light to affect the sensory nerves without involving the motor nerves. It can be made lighter by the addition of 10 per cent. alcohol to 4 per cent. of solution. By regulating the position of the patient's body it is possible to arrest the anesthetic at any point of the spine desired. In all operations in the upper part of the body it is essential to be prepared to perform artificial respiration at any moment. In the cases embraced in this report various anesthetic agents were employed.

Senile Epilepsy

DR. EDWARD D. FISHER, New York: Under this head I include only those cases occurring in adults (who are neither alcoholics nor syphilitics), especially those in the period of life when physical decline has already *begun to manifest* itself. The underlying etiological factor is arteriosclerosis, distinguishing it absolutely from essential epilepsy. There may have been few, if any, preliminary symptoms, beyond some fatigue formerly unusual, or a slight weakness of memory, until, as out of a clear sky, an epileptic attack takes place. The course of the disease varies somewhat with the course of life pursued after the first attack. The succeeding ones vary very much in frequency in different instances. After a seizure there may be a localized serous effusion, but this soon clears up, leaving no trace of paralysis or other impairment. There is probably a general sclerosis of the cerebral arteries, and the attacks are no doubt due to temporary occlusion of the vessels —possibly to venous stasis. The general tendency of the disease is towards dementia or premature senility, frequently accompanied by depression. The seizures may at times be very severe, and, in fact, may end in cerebral hemorrhage of the usual type.

The Routine Use of Autogenous Vaccines (Bacterins) in the German Hospital, Philadelphia

DR. J. C. DACOSTA, Philadelphia: Fifty cases are embraced in the report, of which 17 were classed as septicemia and 33 as local suppurative lesions. By them the following conclusions are suggested: 1. Autovaccines are of distinct service in the treatment of general septicemia, especially in postoperative cases in which surgical measures have been ineffectual. Vaccines are useless in combating a sepsis so intense as to stifle resistance, and in such instances the clinical severity of the infection, rather than the identity of the offending bacteria, is the criterion of prognosis. 2. From the laboratory viewpoint, the prognosis is better in toxemias than in proven bacteremias, and the outlook is hopeless when streptococci invade the circulating blood. 3. Autovaccines produce the best results in local infectious lesions. 4. In the class of infections under consideration autogenous emulsions should be used invariably rather than stock preparations, except in the presence of some acute emergency. 5. The opsonic index cannot be relied on as an indicator for inoculation and reinoculation, which should be governed by the general condition and local signs. 6. The best results follow a moderate initial dose of vaccine, with subsequent doses of greater potency and intervals of from three to seven days between the inoculations. 7. The larger one's experience with inoculation work, the more must one realize how imperfectly the true scope and limitations of vaccine therapy are understood.

The Delayed Menopause; its Dangers and Therapeutic Indications

DR. A. E. GALLANT, New York: In women with healthy reproductive organs the menopause should be established abruptly, at an age dependent on the age at which menstruation commenced; early, if begun late, and late if begun early. The menopause is "delayed" whenever menstruation is continued after the "approximate age" (using the approximately determined beginning of menstruation as a guide) and is associated with uterine flexion, version, fixation or neoplasm, or with tubal disease, syphilis, etc. In delayed menopause the greatest pathological danger lies in the presence or promotion of the growth of fibroid or malignant tumors. The contributory dangers are due to delay: 1. The patient fails to consult a physician, refuses examination, or refuses operation. 2. The physician delays examination, fails to diagnose the condition, or fails to recognize the importance of early operation. The danger signals are (1) atypical hemorrhage, (2) discharge, and (3) pain; signals which, if disregarded, will lead to disaster and death. At the "approximate age" the woman has reached the limit of fecundity; therefore the prophylactic removal of a useless and probably tumor-breeding organ is wholly justifiable, and the one sure method of putting an end to all the threatening dangers.

The Treatment of Parasyphilis in the Light of Recent Research; Paresis and Tabes Dorsalis

DR. T. A. WILLIAMS, Washington, D. C.: I believe leptomeningitis to be always present in these cases. In the treatment of syphilis the tendency at present is to rely almost exclusively on mercury. The iodids are considered of service only in dealing with gummata. I am of the opinion that many incipient cases of paresis and tabes may be cured by using mercurials to the utmost extent which the patient can tolerate. They should be employed by means of inunction or hypodermatic injection, as I have not found administration by the mouth efficient. The important thing is that these patients should be seen early by the neurologist.

SYMPOSIUM ON MATTERS PERTAINING TO THE REVISION OF THE PHARMACOPEIA

U. S. P. 1910; How May It Be Constructed?

Dr. O. T. Osborne, New Haven, Conn.: In opening this discussion it seems to me I can do no better than to elucidate some of my propositions already in print. As regards my recommendations that the new Pharmacopeia should contain such drugs only as are of positive therapeutic value, the decision as to what drugs are to be retained or deleted; and as to what new drugs are to be admitted, might well be left to a committee of five clinicians selected by the U. S. P. Revision Committee. As to the recommendation that it should give official approval to only the best of the official Galenic drugs, and of the salts of such mineral agents as iron and mercury, this also might be left to the judgment of a committee appointed by the revision committee, but one composed of five clinicians and five pharmacists. Every writer of a prescription, and most assuredly every teacher of materia medica, will approve of the proposition that the new Pharmacopeia should give the most simple titles to all new drugs, especially to the synthetic drugs. The heart-rending and brain-splitting attempt to prevent all possible advertisement of a proprietary drug has been followed by continuous damning all over the country, and has forced the ordering of the drug by its proprietary name, much to the profit of the drug promoter.

[Subsequently, the recommendations made by Dr. Osborne were, with some slight modifications, endorsed by the society and ordered to be transmitted to the new committee of revision.]

Revision of the United States Pharmacopeia

Prof. Joseph P. Remington, Ph.M., Philadelphia: The controversy which has been going on recently in the medical and pharmaceutical journals, and even in the public newspapers, concerning the scope of the new Pharmacopeia has developed two clearly marked views. On the one hand, there is a decided movement to curtail the list of articles to be admitted; but a powerful counter-movement has been set on foot to greatly enlarge the number of remedies. Both of these ideas will no doubt be ably championed in the coming convention, but it does not require a prophet's vision to foretell that neither extreme will ultimately prevail, and when both sides have been heard the next committee on revision will undoubtedly admit a selected number of the newest articles and will delete many of the older ones which, in the eyes of many members of the medical profession, have outlived their usefulness. The controversies which have for the most part been carried on in an admirable spirit, have been of great value in clearing the atmosphere, and both physicians and pharmacists will have a much clearer conception of the magnitude of the task before them, though they will have, to guide them, a vast amount of information gathered from all sources. While it will be difficult to always wisely make a proper selection, I have the faith to believe that out of the multitude of counsellors there will come wisdom, and that the ninth revision of the Pharmacopeia will prove to be the best that has been written.

Should the Pharmacopeia Contain Only Useful and Efficient Drugs?

Dr. N. S. Davis, Jr., Chicago: I believe that only useful and efficient drugs should be admitted, and am of the opinion that it would be quite possible for a group of physicians to determine satisfactorily what ones are really useful. Hitherto drugs have been judged by their use, not their utility. I would like also to see an epitome of the pharmacological action of the various drugs inserted in the Pharmacopeia, but suppose we can hardly go as far as that at present. For the good of the physician, as well as the patient, I believe that all compounds should be admitted.

Suggestions for the Pharmacopeia of 1910; a Brief Consideration of the Subject in Its Relation to the Federal Food and Drugs Act

Dr. F. P. Morgan, Washington, D. C.: The three years which have elapsed since this law went into force have offered an opportunity to test the efficiency of the Pharmacopeia as a legal standard, and, as might have been expected, instances have occurred in which the official standards have not proved altogether satisfactory. Among the changes which, in my opinion, would be desirable, are the following: that the proportion of foreign matter permissible in the crude vegetable drugs should be definitely fixed; that powdered vegetable drugs should be admitted; that with hyoscyamus, belladonna and stramonium the requirements as regards mydriatic alkaloids should be made more definite; and that certain tests which have been worked out for copaiba and balsam of Peru should be made official. It is evident, from the standpoint of the efficiency of the food and drugs act, that the larger the number of drugs described in the next Pharmacopeia the better, provided that the drugs are properly standardized. This proviso is of great importance, because the presence in the Pharmacopeia of drugs without standards, or with inadequate standards, is of little or no advantage so far as facilitating the execution of the law is concerned.

Other papers read at the meeting were: "Hexamethylenamin in the Treatment of Otitis Media," by Dr. W. M. Barton, Washington, D. C.; "The Preparation of Tyroid Glands for Use," by Dr. S. P. Beebe, New York; "The Immediate and After Management of the Puerperant," by Dr. Jesse Sharp, Washington, D. C.; "Asthenia Universalis Congenita," by Dr. C. L. Green, St. Paul, Minn.; "The Further Use of Calcium Creosote in Medicine," by Dr. L. Kolipinski, Washington, D. C.; "Some Points in Bacterial Therapy," by Dr. F. E. Stewart, Philadelphia; "Bacterins; Their Present Status in Therapeutics," by Dr. N. P. Barnes, Washington, D. C.

AMERICAN GYNECOLOGICAL SOCIETY

Thirty-fifth Annual Meeting, held in Washington, D. C., May 3-5, 1910

(Continued from page 1714)

Gall-Stones During Pregnancy and the Puerperium

Dr. Reuben Peterson, Ann Arbor, Mich.: Gall-stones are most commonly encountered in women between the ages of 20 and 35. Gall-stones are more common in women than in men. There are reasons for thinking that child-bearing has something to do with the frequency of gall-stones in women. This was borne out by finding that in 542 patients in whom the gall-bladder was palpated during the course of abdominal operations, gall-stones were found to be present in 64, or 11.8 per cent. The percentage of patients with gall-stones, who had borne one or more children, was 75, as against 65.7 per cent. in women who had no gall-stones. In the present series of pregnant patients with cholelithiasis, in nearly one-third of the cases the onset of the attack was at the fifth month of gestation, or at the time when the uterus is approaching the level of the umbilicus and beginning to crowd the intestines toward or on the bile passages. In the puerperal cases the onset of the attack in one-half of the cases was during the first seven days postpartum. Chills and elevation of temperature, associated with jaundice are frequent in gall-stones complicating pregnancy and the puerperium. In the series studied, there was a surprisingly large percentage of pregnant patients with jaundice, 15 out of 25, or 60 per cent. Only one out of the ten puerperal patients had jaundice. The operative mortality for the 23 pregnant patients was 13.04 per cent. The operative mortality in the puerperal cases with cholelithiasis was 11.1 per cent. In the pregnant patients with cholelithiasis more than one-half of the stones were in the gall-bladder alone; the same may be said of the puerperal cases. It is probable that there is no greater tendency for gall-stone operations to interrupt pregnancy than is the case with other abdominal operations during various periods of gestation. It is advisable, when cholelithiasis complicates pregnancy and the puerperium, to choose the operative procedure which can be performed in the shortest possible time consistent with the existing conditions. The condition of the pregnant patient as regards the cholelithiasis should be the determining factor as to when the operation should be performed; whenever possible the operation should be postponed until the child is viable. The diagnosis of cholelithiasis during pregnancy and the puerperium will not be difficult in typical cases if the possibility of the complication be borne in mind. Much reliance can be placed on the jaundice which seems to be more prevalent in pregnant than in non-pregnant women with gall-stones.

DISCUSSION

Dr. W. F. Wakefield, San Francisco: The relationship between pregnancy and gall-stones is interesting. I believe that a large percentage of women have gall-stones, and the curious thing is that in carefully studying the histories of these women in a large percentage of them I could trace the beginning of the symptoms to pregnancy. I think that about 75 per cent. of the women who complain of symptoms of gall-stone disease will date the beginning of those symptoms back to pregnancy. As gynecologists we are neglecting the gall-bladder. The gall-bladder should be examined every time we open the abdomen, and every time we find stones in the gall-bladder they should be removed at that time. It is a mistake to operate on gall-stones during pregnancy if it can be avoided.

Dr. Philander A. Harris, Paterson, N. J.: Any one who operates for gall-stone disease in the course of pregnancy may well wonder whether it is right to do the operation at that time or not, but as near as I can understand from the cases reported, I do not think the decision should depend on whether the patient is pregnant or not. I think the decision should be governed by such other conditions as would govern us in the removal of gall-stones or gall-stone disease, no matter whether it occurred in connection with pregnancy or not.

Dr. Lapthorn Smith, Montreal: I question whether it would be a good thing to operate on a woman for gall-stones who is six months advanced in pregnancy. I think that it is not a good thing to do so at that time because the size of the uterus makes the operation difficult. The pregnant woman should be carried along with morphin and other treatment until she has been delivered, and then she should be operated on for gall-stones.

Dr. W. G. Wylie, New York: I have been watching the gall-bladder whenever I have opened the abdomen through an incision large enough to introduce my hand, and I have found that the percentage of gall-stones is much greater than I had expected. Whenever the gall-bladder is distended with fluid there will be nausea and vomiting after operation, almost without exception in my experience, and when it is flaccid and empty, vomiting is rarely ever severe.

Dr. H. N. Vineberg, New York: A few years ago I was called in consultation in a case of supposed puerperal sepsis. The woman had been delivered ten days before. She was very ill; had a temperature of from 104 to 105 F.; pulse, 120, and complained of pain in the lower part of the abdomen on the right side. She had given no history of gall-stone attacks prior to that so far as one could learn. I examined her carefully and came to the conclusion that the trouble was not with the pelvic organs. I went higher and found a distended gall-bladder. She was transferred to the hospital, was operated on, and the gall-bladder was found full of small stones, with mucopurulent fluid. The woman made a good recovery. I do not agree with Dr. Smith as to the non-advisability of operating on some of these patients during pregnancy.

Dr. Henry T. Byford, Chicago: Undoubtedly many women have gall-stones and may have had them for a long time, pregnancy being merely the cause of the first recognizable symptoms.

Dr. John F. Thompson, Portland, Me.: In January, in my service, I had referred to me from the medical side a patient who was supposed to have had perforation from a duodenal ulcer. The period of illness was about 24 hours. The patient had considerable temperature, and was 3 or 4 months pregnant. The soreness, pain and tenderness gave indications as to the point of election for making the incision. I found perforation of the gall-bladder with stones and pus and some bile, which fortunately were shut off by folds of omentum. The operation was uncomplicated; adhesions were not very dense. With the scissors I removed the edges of the perforation, drained the gall-bladder, and the patient had no interference whatever with pregnancy.

Dr. Henry Hough, New Bedford, Mass.: A month ago I was called in consultation to see a woman in a moribund condition. She had been delivered about ten days before. The first week of convalescence was normal, then symptoms pointed to acute cholecystitis. As the woman was moribund no operation was done. After death several quarts of deeply bile-stained fluid were removed from the abdominal cavity which demonstrated the nature of the case. I have operated in two cases of gall-stones during pregnancy. One in a woman of 23 who was 2 months' pregnant; she had stones in the gall-bladder and in the duct. She also had chronic pancreatitis. When I operated she had just recovered from an attack of acute pancreatitis, as was evidenced by extensive fat necrosis in the omentum. Drainage and removal of the stones resulted in a cure. About one month after operation she was delivered of a three-months' fetus. The other woman was 5 months' pregnant and had acute cholecystitis with gall-stones in the gall-bladder. The gall-stones were removed and she made a prompt recovery, with drainage, and went on to full term.

Dr. Richard C. Norris, Philadelphia: Operations for gall-stones during pregnancy should be determined by the character of the cases. If the case is an aggravated one, the woman should be relieved of the gall-stones independent of the pregnancy, but if it is a case in which we can tide the patient over until labor has been accomplished, it is better to do so. We should apply the same principles of surgery to gall-stones associated with pregnancy as we would to women independent of pregnancy.

Dr. R. Peterson: Dr. Norris has presented in a few words the inevitable conclusion that we must operate on these pregnant women and also on the puerperal woman according to the conditions presented by the gall-stones.

Anastomotic Repair of the Ureter

Dr. Malcolm McLean, New York, said that cases may occur in which end-to-end anastomosis is desirable and preferable to implantation into a slit wound. He described a method which offers a means of securing anastomosis, and at the same time providing for the safe conduct of the urine past the point of repair during the first critical hours after the operation.

President's Address: American Gynecology

Dr. Edward P. Davis, Philadelphia: American gynecology had its origin in the crude obstetric practice of fifty years ago. The necessity for repairing the injuries of labor developed the genius of Sims and Emmet, and American ingenuity added a new branch to surgical science. As obstetric surgery has developed and asepsis was introduced, gynecology has become more and more abdominal surgery. This has been the case not only because better knowledge of obstetrics has lessened the injuries of labor, but because women have those abdominal lesions most easily recognized and most frequently occurring. At present, the modern gynecologist operates on men and women alike, the surgeon in turn performing many operations on women. To-day the tendency of development in gynecology lies in the study of the normal relations of the abdominal and pelvic viscera, the determination of the dynamics of the abdomen and pelvis, and the recognition of those causes which produce abdominal and pelvic ptosis. We have learned that the repair of lacerations of the genital tract does not suffice to cure these cases. The pelvic viscera must be brought into such relation with the abdomen and its contents that the dynamics of the abdomen shall maintain health for the individual, and not disease. Modern surgery having conquered the world of technic, seeks other fields of conquest. The operation for cancer seems to have reached its anatomic limitations, but the cause of cancer remains unknown. Gynecology to-day is especially charged with the task of studying the cause and the mode of growth of malignant disease, so that operation may be wisely chosen and performed. The genital tract of woman gives opportunity to study pathologic processes closely akin to malignant disease. Such are the non-malignant degenerations of the generative organs, of which examples are found in autolysis of the uterus, changes in the Graafian follicles, and corpus luteum, necrobiosis in fibroids, and cystic and calcareous changes in ovarian and fibroid tumors. Protoplasm may thus be studied in its germinal and degenerative changes. The discovery of chorioepithelioma and its identification as a form of malignant disease serve to illustrate this point. Our knowledge of cancer to-day pauses at the phenomena of premature cellular death and degeneration.

In no branch of medicine has so great advance recently been made as in obstetrics. Pathologic chemistry has thrown new light on toxemia and eclampsia and lessened the frequency and mortality of these grave complications of parturition. Obstetrics offers abundant work for the future. Toxemia and eclampsia are but partly understood. It is still not proved that vaginal delivery, after opening the pelvic girdle, is not accompanied by such injuries that abdominal delivery is not better, and even in the repair of lacerations the final word has not yet been spoken. It is still an open question whether in puerperal sepsis we can do more than feed and stimulate the patient. To us is entrusted the physical care of woman in her most important function—the conservation of the race. Our supreme reliance in national crises is the moral sense of the people. But how can this be done unless children be born with a sound brain in a healthy body and trained from the earliest days to a natural life and prompt obedience. If this republic is to endure, its women must bring to its altars not the paste jewels of an artificial luxury, but those gems which made immortal the mother of the Gracchi. Gyncology is an American science, of which America may well be proud. Let us see to it that it serves faithfully the land of its birth.

(To be continued)

SOUTH CAROLINA MEDICAL ASSOCIATION

Sixty-second Annual Meeting, held at Laurens, April 19-21, 1910

The officers elected were noted in The Journal, May 7, page 1555.

Prevention of Blindness

In the House of Delegates Dr. C. W. Kollock, Charleston, made a plea for the enactment of the following bill:

"*Section 1.* Be it enacted by the General Assembly of the State of South Carolina, that should one or both eyes of an infant become red or inflamed at any time after birth, it shall be the duty of the midwife or nurse or person having charge of said infant to report the condition of the eyes at once to the local board of health or county physician of the community in which the parents of the infant reside.

"*Section 2.* That the Secretary of State shall cause a sufficient number of copies of this act to be printed, and supply the same to health officers and health committees, whose duty it shall be to furnish a copy to each person who is known to act as midwife or nurse in the cities and towns for which they have been appointed.

"*Section 3.* Any failure to comply with the provisions of this act shall be punishable by a fine not to exceed twenty-five dollars, or imprisonment not to exceed one month, or both."

President's Address: Need of More Thorough Education

Dr. John L. Dawson, Charleston: I wish to make a plea for the advancement of the education of the medical man. I desire to see in the State of South Carolina a better educated medical student. If you go to our dear old college and look back at its records you will find the theses which were required from students at their graduation and which have been kept by the college. They are remarkable and show a degree of learning that should make the medical student of the present day blush. Many of them are written in Latin, Greek, German and French, and show an amount of research and study beyond the average ability of our present class of applicants for a medical diploma. There are two reasons for this: the first, the men have not the money to take collegiate courses before taking up a medical course, and the second, the young men want to graduate too early. They study medicine to make a living only, by any means in their power, and if this state of things continues medicine will cease to be a profession and become a trade. The tendency is toward specialism, and the passing of that beautiful character, the family physician. In this present day the men in the profession are making a headlong rush after money and reputation, and they have not time for general education. We often hear men say that the study of the dead languages is not necessary for the study of medicine, and that the study of modern languages is not absolutely essential. How many young men starting out to study medicine ever think of studying along other lines? Is the average medical student of to-day the possessor of even an ordinary education, attainable at a high school of college? Money is essential to existence, and the medical man must make his living by his brain and skill, equally as well as the laborer by his muscle and brawn; but brain without cultivation is a poor possession, and the skill of the uneducated is looked on with suspicion. Many of our young men go into medicine for a living too hastily, and as a result we have an overcrowding of the profession.

Every man who raises a son for any profession in life should start with an early education of the boy. Training for the chosen profession should commence with the earliest school days. It would be a splendid thing if each one of us had taken up some special line of study along with medicine—music, art, literature or the languages—whatever is our bent. One needs more than his profession alone to shine in a company of cultivated people. An educated man in a community must elevate the people with whom he associates, and his cultivation raises him in the estimation of his inferiors and he can thereby accomplish much good; it makes his work more acceptable to his equals; it maintains his own self respect. No matter how good a physician one is, how able a surgeon, he needs something more. Cultivation stands for mental gentility. I would suggest that our boards of medical examiners take the matter in their own hands and correct this evil. They should be equally as well qualified to judge of a candidate's general preliminary education and fitness to apply for a degree in medicine as they are to judge of his medical education only. I suggest that this association take this matter up for serious consideration.

Serotherapy of Epidemic Cerebrospinal Meningitis

Dr. Charles Hunter Dunn, Boston: Flexner, as one of the committee appointed by the New York health department, investigated the epidemic of 1904 and made a careful study of the pathogenic properties of the diplococcus, showing its brief vitality in cultures, its wide variation in virulence and the rapid autolysis produced by an enzeme which is distinct from the intracellular toxin. Flexner's first experimental work on monkeys and some of the other lower animals did not seem very encouraging toward producing an antiserum, for endotoxins rarely produce sufficient antibodies to neutralize the toxin in an acute infection. But as the diplococcus is easily influenced by unfavorable conditions, and as the curative agent can be applied directly to the lesions, it seemed possible that serotherapy might be successful. It was next demonstrated that immune serum from monkeys would protect infected monkeys. Then a horse was immunized and its serum used for man, as follows: after lumbar puncture, inject through the same needle a quantity of serum equal to the amount of spinal fluid withdrawn. This procedure is carried out on four successive days.

An analysis of 400 cases by Flexner and Jobling shows that the serum treatment of meningitis reduces the mortality from 75 to 25 per cent. This serum is not on the market. It may be obtained without cost from the Rockefeller Institute by anyone who can satisfy Dr. Flexner as to his agility to use it properly, to make the necessary bacteriologic examinations, and to send in an accurate clinical report. Of course, the amount of serum is limited and cannot supply the whole country.

In my series of 86 cases, embracing all types of the disease, 72 per cent. of the patients recovered. These cases, as well as those analyzed by Flexner, show strikingly the advantage of the early use of the serum. Ordinarily, the vomiting, high temperature and mental symptoms disappear rapidly, leaving the rigidity of the neck and Kernig's sign to subside gradually.

The diplococci in the spinal fluid at first become intracellular and then disappear entirely. And last but not least, the occurrence of the much-dreaded sequelæ is greatly diminished.

Pulmonary Tuberculosis: The Persistent Need of Earlier Diagnosis

Dr. L. B. Morse, Hendersonville, made a strong appeal for earlier diagnosis of tuberculosis, rather than a reiteration of the means by which such diagnosis is made. He emphasized the fact that, in spite of all that has been written in recent years, the average physician does not diagnose pulmonary tuberculosis in its incipiency. The reasons ascribed were believed to be largely personal. Timidity in sufficiently exposing the patients to examine them properly was thought to be a common reason for not carefully examining individuals. He condemned the idea that patients do not want exhaustive examinations, and that examinations render patients oversolicitous and introspective. Patients should be told frankly the facts in these cases, as insuring a closer obedience to the necessary change in the mode of life so essential to a cure. Lastly, he enumerated the conditions of life, and of the individual, wherein a careful man would be more apt to look for tuberculosis.

Dont's in Medicine and Surgery

Dr. Walter Cheyne, Sumter, read the following axioms:

1. Don't fail to make an exhaustive physical examination in every patient who comes to you. This means heart, lungs, liver, kidneys, abdominal palpation, urine and sputum, when necessary. Your error may not only mean the loss of your reputation, but also the death of your patient.
2. Don't delay an operation for appendicitis after the diagnosis has been made. Don't be influenced by ignorant people to wait until the patient is in danger of death. Pus walled off or walled in you will drain. The removal of the appendix in most cases may be deferred when drainage is established.
3. Don't think an examination of urine is made by intuition. Fresh reagents, exact methods which certainly include filtration, are necessary for you to make a positive statement to an insurance company or to a patient.
4. Don't be surgically careless after a pus case; disinfect as you would after a post-mortem. Pus clings to all tissues; pus germs are not harder to kill than most other germs; therefore, take proper precautions to kill them on your hands and on the places where they originated, if possible.
5. Don't claim to know every skin eruption you see. Perhaps five men in the United States do know such eruptions. If you are doubtful, say so; it won't hurt you, and may do the patient good.
6. Don't tell a man he is cured of gonorrhea unless you know. If you don't know and you tell him he is cured, you may cause a woman's death.
7. Don't think you know all medicine and surgery until you have studied the methods in seven different cities and have practiced conscientiously for twenty-five years. Even then you may turn over in bed at night several times and have doubts as to your knowledge.
8. Don't feed poll-parrot style in typhoid fever. You can starve a patient to death in typhoid as well as have the fever kill him. Anemia must be combated as well as the fever. Better higher fever than a feeble heart.
9. Don't forget that scientific knowledge, added to scientific equipment, plus a practical knowledge of human nature, are the trio necessary to professional success.
10. Don't minimize the value of membership in a medical society. The charlatan cannot get in. Count the number of successful professional men you know who are not members of their state association.
11. Don't use a drug, unless you know it is necessary. If in doubt, leave out the medicine.
12. Don't forget in medicine or surgery the Golden Rule, "Do unto others as you would that they should do unto you."

The Present Status of Cancer Education

Dr. Southgate Leigh, Norfolk, Va., chairman of the Committee on Cancer Education of the Tri-State Medical Association of the Carolinas and Virginia, appeared before the society chiefly for the purpose of enlisting the cooperation of its members in the campaign of cancer education which the committee is instituting in these states. He called attention to the nature of cancer, its wide prevalence and its incurability in the later stages. Cancer, he said, is preventable or curable in at least 95 per cent. of cases if taken in time, and yet, largely from ignorance and misunderstanding on the part of the public, 90 per cent. of cancer patients die. The real problem is the education of the profession and public alike in the prophylaxis and early treatment. He called attention to the good work of the American Medical Association in disseminating knowledge about "cancer quacks," briefly reviewed the work done by Winter in Koenigsberg, Germany, and referred to various papers published in this country. He also discussed the advisability of disseminating useful information to the public through boards of health, public clinics and women's societies, by distribution of circulars, and also by appropriate articles in public press. He emphasized the fact that the hearty cooperation of the general practitioner was most important.

Things the Profession Should Know About Cancer

Dr. Le Grand Guerry, Columbia, read a paper on this subject.

DISCUSSION

Dr. J. S. Horsley, Richmond, Va.: The earlier the diagnosis is made, the more difficult it is, but the greater the patient's chance of being cured. Anyone could make the diagnosis in the late stages, but then the case is inoperable and diagnosis can be of no avail. Statistics have shown that the opportunity for cure of cancer by operation decreases with the advance of the disease in almost mathematical precision. For instance, if a cancer of the breast is taken in the early stage, before the involvement of the skin or the glands, radical operation will cure permanently more than 75 per cent. By cure is meant that these patients are well without recurrence 3 years or more after the operation. When the glands in the axilla are involved the percentage drops to 35 per cent. When, in addition to this the skin is involved, the ratio of cure is less than 20 per cent. When the supraclavicular glands become affected there are only from 5 to 10 per cent. of patients cured, and operation is hardly justifiable. Each of these stages represents a definite state in the progress of cancer, which results from delayed operations. It is the duty of the physician to insist on every patient with a growth, the nature of which he does not know, being examined and the diagnosis definitely determined. If he waits until the tumor "develops" he is sacrificing the patient's chances of life with every day's delay. The most prominent single symptom of cancer is the absence of pain. A patient will rush to a doctor with a boil because of pain, but with a growing cancer, which gives no pain until the late stages, the patient will frequently delay consulting a physician until it is too late. If people could be brought to learn that a tumor without pain is more dangerous than a growth with pain, many more lives could be saved. Exploratory incisions for diagnosis of doubtful tumors is always dangerous, unless immediately followed by radical operation. The surgeon should study his own tumors and be his own pathologist, by noting the appearance of the growth at the operating table and following it through the laboratory, noting its microscopic appearance, he will be in a position to decide the nature of a similar tumor the next time he meets it at the operating table, for he will recall the microscopic picture of other tumors that looked and felt like the one he is dealing with. The surgeon should carry practical knowledge of pathology in his own head, and not in the head of some one else, for delay in the pathologic report frequently means that the patient has lost the only chance for permanent cure.

A Plea for Medical Inspection of School Children in South Carolina: Report of the Work at Seneca

Dr. E. A. Hines, Seneca: While medical inspection of schools has made rapid progress in many parts of the world, the southern states appear not to have become interested until very recently. New Orleans and Atlanta each inaugurated medical inspection in 1909. Seneca was the first place in South Carolina to put in operation such a system, Sept. 23, 1909. The examining board consisted of two general practitioners, two dentists, an eye and ear, nose and throat specialist and a secretary. This combination, with the assistance of the teaching staff at times, resulted in a thorough examination. In all the more serious cases the children were treated by or on the advice of the family physicians. I examined also a representative number of negro school children; 90 per cent. had bad teeth, skin diseases very prevalent, but other defects were similar in general to the whites. I also examined a representative number of cotton mill operatives' children; 90 per cent. of these had bad teeth; not one had a tooth-brush. Other defects were not very different from previous reports. Laws should be enacted looking to enforced medical inspection in South Carolina.

An Epidemic of Beriberi at Convict Stockade, Ten-Mile Hill, Charles County

Dr. Allen J. Jervey, Charleston: Early in March there developed within a fortnight 17 cases, which were diagnosed beriberi, and the patients sent to the state penitentiary as unfit for work on the county roads and as possible sources of infection to the remaining 14 prisoners. They presented about the following pictures: An edema, starting in most cases about the calves of the legs, with some pain, numbness and paresthesia in this region. The edema was not of the boggy type, but seemed resistant to pressure, and extended rapidly until in the most marked cases it had involved thighs, abdomen, scrotum, front of chest and face. The onset was accompanied with a general feeling of lassitude rather than a distinct malaise. Temperature normal; urine negative. In the more advanced cases there was accelerated pulse, or a pulse which after the least exertion would reach 120 and over. These individuals showed a dilated heart and it was hard to distinguish the heart sounds. Relative murmurs and venous pulsations in the neck were observed. The gait was tired, slow and dragging, but there was no ankle-drop or wrist-drop. Knee-jerk was diminished or lost; in one case noted it was increased. Hookworm ova were found in two out of three patients examined; no other intestinal parasites were noted. One-half of the patients showed white fur coating on tongue. There was a general tendency to constipation.

Is beriberi a new disease here, and what is the source of the infection? I think that beriberi is and has been for several years an endemic disease in the low lands of South Carolina. During the past two years I have seen three distinct outbreaks of what I now know to be beriberi. This statement is borne out by my inspection of the previous attending physicians' records, in which I find beriberi called by various names, as "malaria," "acute nephritis," "cellulitis of legs," "myositis," "undiagnosed," "swollen limbs" and "dropsy." The first patient I treated, in 1908, was very anemic and, finding hookworms, I gave thymol and iron, which brought about marked improvement, but possibly the moving of the camp to a higher elevation may have had something to do with the improvement. In September and October there were two deaths, the first from edema of the lungs as the immediate cause, and the second, rather sudden, possibly from involvement of the vagus. He had been complaining for a few days, had edema and pain in the calves of the legs, but did not stop work. Careful postmortem revealed only an increased amount of fluid in the pericardium and abdomen. Four of my patients went to Columbia and the condition was diagnosed by Dr. Pope as identical with that in patients who come up from the phosphate fields and which was spoken of as "phosphate sickness."

The cause of the infection is yet in a theoretical state. The convict camps are high, sanitary and dry, and are well ventilated. The drinking water is pure. The rice theory does not apply, as rice is excluded from the dietary of the convicts. We have in this camp neither heat nor moisture—supposed to be the cause of this disease. Prior to these outbreaks one gang, composed of the more intelligent negroes, who handled the animals and the road machines, was known as the road gang; the others were concerned with the drainage work chiefly; and their duty is ditching water of various depths in the low, foul bottoms that need drainage. The first ones attacked in each outbreak belonged to the ditching gang, and the symptoms appeared about six weeks after each exposure.

DISCUSSION

Dr. J. C. Sosnowski, Charleston: There are two types of beriberi—the wet and the dry. As an intern in the city hospital at Charleston six years ago I had the good fortune to see an epidemic of beriberi of the dry type. This epidemic occurred on a ship coming from Chili. When the vessel reached Charleston 19 men were infected and 1 died. Most of them had a slight toe-drop and some paresthesia and numbness; but 4 of these were very ill. The one who died developed sometime before he died a marked diarrhea, which nothing could check. The next spring, in the same neighborhood in which Dr. Jervey found his cases, I found a case of multiple neuritis of the dropsical type. I could not make diagnosis of beriberi, as I had only one case, although I thought it was that. The patient told me, however, that there were several similar cases in that neighborhood. Since then I have heard of an epidemic of dropsy. I think the disease has been with us for a long time, and those affected in this neighborhood seem to have the wet type, which would lead us to suspect there are two varieties, not only clinically but etiologically. I think it is probable that when we find the cause we will find that this is an infectious disease. I have heard that there have been epidemics of dropsy throughout the low country for several years, and it is most probably the same disease. I think, as does Dr. Jervey, that the line for us to follow would be to search for some agent of transmission which lives in the ditch water, because every case which we have seen has developed among the negroes who have worked in the mines or ditches.

What Has Been Done for the Prevention of the Increase of Blindness, and What Can Be Done

Dr. Charles W. Kollock, Charleston, cited the work which has been done in various states, mentioning especially New York, Massachusetts and Ohio. He gave an account of the good work that is being carried on by the New York Association for the Prevention of Blindness, and dwelt especially on the literature that is being widely distributed to the laity, the public lectures delivered and the amount ($5,000) that was appropriated by New York State for this work last year. He quoted the law of South Carolina for the care of new-born infants whose eyes should become inflamed after birth, and criticized it because it applied to cities and towns of 1,000 inhabitants and over and not to the whole state. He urged the amendment of this law at the next meeting of the association, so that it would apply to the entire state. He quoted the statistics of blind persons in various blind institutions who had been blind since birth, and among them that of the institutions at Cedar Springs, S. C., where out of 78 persons 23 have been blind since birth. He spoke of the large negro population in South Carolina, among whom eye diseases are rife and who are eminently careless in all health matters. He urged strict laws and education for these people. He quoted the number of births in Charleston from July 1 to Dec. 31, 1909, that of 213 whites 155 were attended by physicians and 58 by midwives. Out of 225 colored births 30 were attended by physicians and 195 by midwives. He mentioned that those midwives were not only ignorant, conceited, dirty, but very superstitious, and that more stringent laws should govern them. He said that all contagious and infectious diseases should be reported to the health office, according to existing laws, but doubted if we were ready to report a case of gonorrhea or syphilis or gonorrheal ophthalmia, but that there could be no doubt that publicity would lessen the number of cases. He declared that it was a shame that innocent women should be exposed to the danger of those diseases and that every man who desired to marry should be made to present a clean bill of health before obtaining a marriage license.

Uncinariasis in the Negro

Dr. W. J. Burdell, Lugoff, gave some interesting statistics in regard to hookworm in the negro. His tests were as follows:

Total number of stools examined, 226, from as many individuals. Hookworm ova in from 145 to 65 per cent.; persons examined ranging from 2 to 60 years.

Stools from 178 persons under 20 years of age, 126 contained hookworm ova, 70 per cent.

Three men over 50 years of age showed hookworm ova. They came from the clay lands of South Carolina; 200 individuals presented no symptoms of any disease; 5 were tuberculous and all these had hookworm; 21 "rickety" children under 5 years of age were infected with hookworm.

Of the 226 there was a history of ground itch in 190 cases, 84 per cent.; all went barefoot in summer.

Of 92 girls under 20, 61 were infected; of 86 boys, 65 were infected; 8 men and 11 women over 20 were infected.

He was treating the 5 tuberculous patients as nearly according to the recognized modern method as possible, with this class of patients, and getting very poor results. After finding the ova and removing the worms, three have greatly improved. While not claiming that tuberculosis can be cured by thymol, he stated that one of the reasons tuberculosis is so prevalent, and its course so rapid in the negro, is the fact that he has uncinariasis in what may be called a latent form, and tuberculosis or any other infection may overcome the partial immunity the race has acquired for hookworm, and hence there is a double infection. In the sand-hill district of South Carolina about 65 per cent. of all the negroes have hookworm; uncinariasis is latent in a majority of the negro race, and in the presence of other infections the uncinariasis becomes active and lessens the natural resistence. Uncinariasis plays an important rôle in the causation of rickets in the very young negro child. Hookworm is one of the first causes of the high mortality from tuberculosis in the negro race.

Report of a Case of Appendicostomy by a Method Devised by Dr. Pettyjohn of the Marine-Hospital Service

DR. L. A. GRIFFITH, Columbia: This operation was first reported by Dr. Pettyjohn in THE JOURNAL A. M. A., March 14, 1910. The abdomen is opened over the right border of the right rectus muscle, the appendix located, a stab wound made over the appendix and the appendix drawn through this stab wound. The abdominal cavity is quickly and effectively walled off. The appendiceal stump is short and straight. Irrigation can be begun at once. This method has all the advantages of appendicostomy as heretofore done, without the bad features. With this method it does not matter if the stump sloughs, and if a cecostomy is indicated this incision of Dr. Pettyjohn's is the most desirable. The danger of hernia and infection is greatly reduced. In the case reported the patient was probably syphilitic. Improvement was rapid, though he had not responded to medical treatment, and had been ill with dysentery more than one year.

DISCUSSION

DR. J. SHELTON HORSLEY, Richmond, Va.: Cecostomy has an advantage that appendicostomy does not present. The chief advantage, it seems to me, is the location of the cecum, which is in many cases in proximity to the anterior abdominal wall. The appendix has no definite location, but it is more frequently than otherwise found behind the cecum, and in order to bring it up, as Dr. Reed has pointed out, it is necessary to turn over the cecum, which makes a kink or valve and interferes with drainage. It seems to me that we are too likely to look on the appendix as something that has to be made some use of, besides securing the surgeon a fee, and it would probably be a little more preferable to take off the appendix in those cases and treat the stump, simply; tie a string around it without a purse-string suture, which cuts off the blood supply and complicates matters unnecessarily. Let the cecum fall back and bring up the anterior wall of the cecum, make a hole in it, put a purse-string suture around the hole, insert a rubber tube, tie the purse-string, and we have drainage which is very much better and more direct.

MEDICAL ASSOCIATION OF THE STATE OF ALABAMA

Annual Session, held at Mobile, April 19, 1910

The President, DR. W. M. WILKERSON, Montgomery,
in the Chair

A list of the officers elected was given in THE JOURNAL, May 7, 1910, p. 1549.

Uterine Fibroids Complicating Pregnancy

DR. R. S. HILL, Montgomery: Although these tumors are found in 20 per cent. of women beyond 30 years of age by postmortem examination, Pinard found them in only 84 cases out of 14,000 pregnancies. The reason for the latter is that the ordinary obstetric examination does not reveal the presence of the tumors unless of considerable size, and that many women with them never conceive. The diseased condition of the tubes, which is present in 50 per cent. of these women, is responsible for the increased sterility and the frequency of ectopic pregnancy in these women. Abortions, which are frequent, are due more to abnormal changes in the uterine endometrium than to pressure of the tumor. The tumor is liable to undergo degenerative changes, simple or sarcomatous. I do not think that the tumor ever disappears, although it may flatten out, if intramural, as pregnancy advances and give the impression of having done so. In treatment, I would oppose abortion on the grounds that it is not curative, and on account of the liability of infection and hemorrhage, making it about as dangerous as the more radical operations. Myomectomy should be done whenever possible. Not only subserous but intramural tumors may be removed by myomectomy. Should hemorrhage become uncontrollable, or should there be a number of tumors present, hysterectomy should be done. However, no operation should be undertaken if the tumor is out of the pelvis or can be lifted out, provided the woman can be kept where surgical measures can be instituted on short notice should conditions arise calling for them.

DISCUSSION

DR. M. E. CONWAY, Talladega: Some time ago I had a case of fibroid tumor of the uterus which was complicated by placenta prævia. I reached the woman in about twenty-two minutes after I was called and found an alarming hemorrhage. As she was likely to die from hemorrhage, I split the wall of the uterus up to the uterine artery and delivered a seven-months' child. The child is living to-day. The tumor I removed was pedunculated, but the operation was done subsequently and not at the time the child was delivered.

DR. I. L. WATKINS, Montgomery: It is essential to make an accurate diagnosis and determine the location and character of the tumor which complicates pregnancy. A careful examination should always be made of patients who have fibroid tumor or tumors complicating pregnancy. Such a patient should be kept under constant observation and attended to promptly if necessary. Women with good-sized fibroid tumors in the uterus are delivered of babies but sooner or later it may become necessary to operate on some of them for the removal of the tumors in order that pregnancy may go on to term. When a fibroid tumor so interferes with pregnancy as to cause alarming symptoms it should be removed, as temporizing treatment only increases the possibility of infection.

DR. A. L. STAVELY, Washington, D. C.: With regard to myomectomy, I believe in being rather conservative in the treatment of these cases in which the tumor involves the fundus or upper part of the uterus, or even when there is a pelvic growth. I think it is well to wait until pregnancy is well-advanced because these tumors will sometimes rise in the pelvis and labor will terminate without any complications. I operated on one woman in the seventh month of pregnancy for the removal of a large sessile tumor at the base of the uterus or cervical junction. To get at it, I had to raise the uterus from its bed, and then enucleated the tumor.

Opsonin and Immune Sera

DR. H. T. LAY, Montgomery: A moderate dose of vaccine, such as would generally be the most useful dose in connection with a chronic infection produces, after a comparatively short negative phase, a positive phase, which may occur on an average and extend over the interval between two successive inoculations undertaken about ten days apart. A smaller dose would produce an immediate positive phase, but a positive phase would not be maintained for more than a very few days. An excessive dose would produce a negative phase which would last through a large part, if not through the whole of the interval, which usually elapses between the two inoculations.

Nausea of Pregnancy

DR. GEORGE H. FONDE, Mobile: To present the treatment and its principles, I shall recount the salient features of the Lenhartz treatment for peptic ulcer, which, in the treatment of nausea of pregnancy will call for such modifications as the individual condition of the patient and the principles mentioned may logically determine: First, the patient should rest in bed, with an ice-bag over the stomach, the object being to bring about general rest, and especially of the dynamic and secretory action of the stomach. Second, sweet milk containing a tablespoonful of lime water to the goblet of milk—two tablespoonfuls at each feeding—should be given every hour; the patient should be given the food from a teaspoon and not allowed to feed herself. The milk should be packed neatly in ice, and administered ice cold. Each day the quantity of milk given may be increased by two tablespoonfuls at each feeding—there should be two-hour intervals, in feeding at night. By this increase it is but a short time before the patient is getting three or more quarts of milk daily. In the Lenhartz diet on the third day raw eggs are stirred in the milk, and thereafter on every third day an additional article of diet is added until the patient is given much more food than is needed for the average workman, with the result that the general strength and weight, together with greater resistance of the patient to all morbid conditions obtains, especially in vomiting of the nervous and functional type, such as we so frequently have in the nausea of pregnancy. The objects of these measures in the Lenhartz treatment are obviously explained on a physiologic basis. The excessively and constantly secreted acid gastric juice is neutralized by the milk, forming a bland peptone which soothes the stomach mucosa. The intolerance of the stomach to any solid or any volume is gradually overcome by the minute feedings so gradually increased. The patient being fed by the nurse rather than allowed to feed herself, together with the frequency of feedings, satiates the craving and lowers the psychic stimulus to gastric secretion, which is a great factor in pregnancy as in ordinary hyperchlorhydria. The liver, kidneys and heart and, in fact, the entire system are spared the irritation of toxic matters formed in the stomach and duodenum; while the system is being best nourished, the emunctories are being flushed and nurtured. When combating the hyperchlorhydria by the frequent sips of milk in small quantities, it will generally not be necessary to deny the patient regular meals, but as the periodic flow of gastric fluid attendant on regular meals is often in excess of the albuminous coefficient contained in such meals it is my experience that the patient will need to take the iced milk in teaspoonful sips within a very few minutes after the regular meals. In the treatment of such disorders of pregnancy, I would not overlook the value later of general hygienic and dietetic measures, with fresh air, exercise, and agreeable occupation whenever the condition of the patient will permit.

DISCUSSION

Dr. George E. Pettey, Memphis: A certain number of women die from excessive vomiting at pregnancy. I give strychnin to keep up active peristalsis, then ipecac and a little belladonna, and some of the secretion-producing agents to overcome the acid condition of the stomach, which does not appear again to amount to anything so long as active peristalsis is kept up.

Dr. J. S. McLester, Birmingham: The livers of patients who die from the toxemia of pregnancy show changes similar to those observed in acute yellow atrophy of the liver. I believe that the absorption of toxins from the intestinal tract is the primary cause of the condition.

Dr. H. S. Ward, Birmingham: Vomiting of pregnancy, acute yellow atrophy of the liver, and acidosis are so blended one into the other that it is difficult to think of one without thinking of the other. Within three days after vomiting sets in in the pregnant woman one is able to detect acetone in the urine, and if starvation continues many days more, one is almost sure to begin to have autolysis of the liver cells, with all the bad symptoms coming on with an absolute condition of acidosis. This condition is found not only in pregnancy, but in typhoid.

Diagnosis of Painful and Swollen Joints in Children

Dr. J. Ross Snyder, Birmingham: A diagnosis based on joint symptoms alone is entirely untrustworthy. There are few pathologic conditions that can be correctly diagnosed by an examination that includes only the site on which symptoms are most marked. Disease of the joints arising shortly after birth, that is, in the first weeks, and not later than the middle of the second month, is due to septic infection through the umbilicus or to a gonorrheal infection. A form of bone syphilis appearing shortly after birth, usually before the sixth week, is that of an osteochondritis or epiphysitis. The humerus, the radius, and the ulna are the bones most frequently affected, but the disease may appear at other places. In tuberculous knee joint disease there is warmth, obliteration of the depressions on either side of the ligamentum patellæ and atrophy of the thigh and leg, enough almost to confirm the suspicion aroused by the bent knee limp displayed by the child. The frequent mistake is to credit this lameness to injury and to allow the condition to remain without being kept under close observation or treatment. In the diagnosis of tubercular joint lesions, the *x*-ray is regarded of great assistance by some good men. Others equally prominent in the profession minimize its advantages. The tuberculin test is another diagnostic aid which is of disputed usefulness in this particular class of cases.

Chronic Gastromesenteric Ileus

Dr. A. L. Stavely, Washington, D. C., gave a brief summary of gastromesenteric ileus in general, its history, its anatomy, its etiology, and its treatment, and said in part:

In carefully reviewing the literature I have been able to collect 7 cases of the chronic type, including 2 of my own, all of which have been identified as cases of chronic gastroduodenal dilatation. A number of other cases were found in which gastric dilatation was recognized, and in which the symptoms corresponded very closely, but they were not sufficiently conclusive to justify classification. My first case followed an operation about 9 years before, and severe symptoms continued up to the time the woman came under my care in 1907. I anastomosed the duodenum with the jejunum anterior to the mesenteric ligament with complete relief from the symptoms. This is the first time such an operation has been performed for this trouble. The second case was a mixed one due to the presence of a gall-stone, which masked the symptoms. The gall-stone was removed and for a time, until the patient left the hospital, she was free from any discomfort. Then the symptoms recurred intermittently for two weeks at a time up to the present. To try the effect of posture and also to strengthen the diagnosis, I had her take the knee-chest position when the stomach swelled and she reported that after about 10 minutes the symptoms had disappeared. In my table I include 4 cases that are not verified, making 11 in all; 7 patients died of the condition; 4 had been operated on. There were 3 cures, one of them my own.

Treatment of Pneumonia

Dr. Henry Green, Dothan, summed up the treatment of this disease in the following words: A well-ventilated room, isolated as nearly as possible. Rigid prophylactic measures, such as disinfection of sputum and other excretions. The selection of the most intelligent nurse available and the limitation of company. Nourishment of the most palatable and easily digested sort, and medical treatment to be largely for the relief of conditions and symptoms that may arise.

DISCUSSION

Dr. J. F. Jenkins, Piper: I have noticed that many patients with pneumonia will recover if we leave them alone. Of course, we should pay attention to good ventilation, hygiene, nourishment, etc. Medicine should not be given to these patients in a routine manner, but only when symptoms arise. When the heart is weak, strophanthus or strychnin is indicated, and when the skin is bluish nitroglycerin may be used.

Dr. L. W. Roe, Mobile: There is one standard for the treatment of pneumonia, and that is fresh air. Several years ago, when I was practicing medicine in a milling camp, I had the misfortune to have a great many cases of pneumonia among negroes. These negroes were placed in log cabins or rudely constructed houses, and in the winter there was no means of procuring anything like a warm room, regardless of what I did these patients recovered.

Dr. Hugh Boyd, Scottsboro: The prophylaxis of pneumonia is a little different in the city from what it is in the country. People in the city have a better system of health laws and carry them out better than do the country people. Country people need to be educated in regard to the dangers of pneumonia, and when there is a case of pneumonia in the house the rooms ought to be fumigated afterward just as much as after typhoid or tuberculosis. When there is a weakened condition of the heart it is well to use digitalis.

Dr. J. S. McLester, Birmingham: Fresh air is the main thing in the treatment of pneumonia. The toxin of pneumonia seems to have a special affinity for certain nerve centers. It affects the Gasserian ganglion. In certain cases it causes paralysis of the splanchnic nerve and complete loss of vasomotor tone in the abdominal cavity.

Dr. Frank S. Meara, New York: In New York we put patients with pneumonia out of doors. When treating them in the hospital we open all windows wide and properly cover the patients, and they do remarkably well with fresh air treatment.

Dr. Henry Borst, Silver Hill: A good deal of harm is done patients with pneumonia from indiscriminate visiting and in robbing these patients of the fresh air which they should have.

Dr. R. M. Cunningham, Birmingham: Pneumonia is an infectious disease. Over-work, mental anxiety, exposure to cold, and other things which reduce the resistance of the body invite the pneumococcus. In the treatment one should start in with the idea that pneumonia is a self-limited, infectious, toxemic condition, with the resisting power of the body diminished. The factors which contribute to heart failure in pneumonia are toxemia, increased work that the right side of the heart has to do because of the consolidated condition of the lung, and heart clots. One of the most important things to prevent cardiac thrombi and to overcome exhaustion and collapse is the infusion of salt solution.

Value of Employment as Treatment in Certain Neuroses and Psychoses

Dr. William D. Partlow, Tuscaloosa: Employment is of considerable value in the treatment of those mental and nervous states in which worry, anxiety and kindred sensations are present, because it provides mental diversion and promotes physical health.

DISCUSSION

Dr. H. S. Ward, Birmingham: If we can find something that will interest these people, something that will get them out of themselves, they will forget their aches and pains. Those nervous people who are broken down from over-work are suitable for the rest cure.

Pellagra

Dr. E. M. Mason, Montgomery, gave a brief summary of the present knowledge of pellagra. He briefly outlined the morbid anatomy, and in discussing the symptoms called attention to the extreme variability in onset and sequence, as well as severity. A low temperature, he said, was not unusual, associated, as a rule, with a disproportionately high pulse rate. He reported the results of blood examinations in a number of cases. These blood cultures had been uniformly sterile. The blood picture had shown nothing more than a secondary anemia, as a rule. He warned against accepting a large mononuclear increase as caused by pellagra without first excluding malaria, and uttered a similar warning with reference to helminthiasis in cases that show eosinophilia. He pointed out the ease of diagnosis in typical cases, but warned against hasty diagnosis in unusual forms, and mentioned the diseases that may have to be excluded. He though that a lower death-rate than the asylum reports of 60 per cent. might be expected in early, uncomplicated cases, in private practice. There was no specific medication for the disease he said, but much might be expected from good food, rest, proper hygiene and change to cold, dry climate. Arsenic was to be preferred to other drugs. Only mildly antiseptic lotions should be used for the skin lesion. Cold baths, packs and douches should be used for the nervous manifestations. Serum therapy had been disappointing and little was to be expected from it. Finally, he called attention to pellagraphobia as a condition that he had frequently seen in both men and women, and advised a spirit of cheerfulness and optimism on the part of the physician in order to counteract the hopelessness and despondency that the popular dread of the disease had engendered in the minds of the people at large. His personal experience embraced the study of about 75 cases.

DISCUSSION

Dr. H. P. Cole, Mobile: Speaking of pellagraphobia, I have in mind a patient who came to one of the infirmaries here with a burn on the back of his neck, which was simply a dermatitis, but he came 150 miles to be treated for pellagra. Another patient in Tipton, Georgia, was treated for 2 months for pellegra, came to Mobile markedly anemic, insisted on transfusion for what he thought was pellagra, went home and died in three weeks from tuberculous peritonitis, and the case was listed as a death from pellagra.

Intubation in Laryngeal Diphtheria by the General Practitioner

Dr. Andrew M. Stovall, Jasper, reported eleven cases in which he resorted to intubation, with one death, and said a lesson should be learned from the case he lost by waiting for pronounced cyanosis to assert itself. He said: Do not temporize too long, but intubate as soon as signs of labored breathing are manifest. I would not advise the general practitioner, who is so situated as to command the aid of a specialist, to attempt this operation as a routine. But the physician of the rural districts, far removed from the specialist, should so equip and train himself as to be prepared to do this work when the urgent case presents itself.

SYMPOSIUM ON UNCINARIASIS

Dr. Herbert P. Cole and **Dr. Gilman J. Winthrop**, Mobile, presented a joint paper in which they reached the following conclusions:

1. Uncinariasis must be considered not merely a disease of the lower classes, but affects to a large extent all individuals living in the state.
2. The number of infected individuals showing practically no gross symptoms warrants the routine examination of the stools of all persons from infected districts.
3. Further study of the prevalence of hookworm disease among the better classes of people will aid in the final estimate of the extent of the disease in the south.

Dr. George Dock, New Orleans, spoke on the prevention and treatment of hookworm disease.

Dr. Charles W. Stiles, Washington, D. C., gave an address on uncinariasis illustrated by numerous stereopticon views.

Dr. Henry G. Perry, Greensboro, pointed out the importance of instituting an educational campaign against hookworm disease.

Dr. S. M. C. Howell, Midland City, discussed the etiology, pathology, symptomatology, and diagnosis of hookworm disease.

Cesarean Section

Dr. William D. Jaines, Lafayette, reported the case of a woman, aged 22, on whom he did a Cesarean section and delivered a living child at full term. Both mother and child were in perfect health. In connection with the operation he resected a portion of each tube to prevent future conception, but the patient told him a short time ago that she had been menstruating regularly for some time.

Indications for Removal of Faucial Tonsils and the Technic

Dr. Frank M. Thigpen, Montgomery, said that in his experience no evil effects have followed the removal of diseased tonsils, and that when the operation is done in a clean, careful and correct manner, the operator will be rewarded not only by the relief given the patient, but by the satisfactory results of his work.

Acute Endocarditis

Dr. William W. Harper, Selma: The treatment of ulcerative endocarditis is preventive. Since it is caused by gonorrhea and septic organisms, we should seek to cure these diseases as promptly as possible. The hope of the future lies in serotherapy. In all streptococcus infections, we should give antistreptococcus serum a thorough trial. Doctors should impress on the laity that gonorrhea is a serious disease and needs prompt and thorough treatment. In the acute stage small and increasing doses of the bacterins are giving good results in the hands of some.

Diagnosis of Obscure Cases of Appendicitis

Dr. Mack Rogers, Birmingham, drew the following deductions:

1. There is a normal involution of the appendix.
2. This is accompanied by a fibroid degeneration of the normal structures of the organ.
3. In this process the nerve fibers are the last to be eliminated and are, therefore, entrapped in the meshes of the contracting fibroid tissue and irritated.
4. This irritation manifests itself both by pain and reflex action upon other organs.
5. This pain calls out and maintains a permanent hyperleucocytosis that protects the appendix from infection.
6. This reflex action may manifest itself on almost any of the vital organs of the economy.

A CONFERENCE OF OPHTHALMOLOGISTS WITH ORGANIZATION OFFICIALS ON FAMILY PHYSICIAN REFRACTING

By Leartus Connor, M.D.
DETROIT

The promotion of family physician refracting calls for the cooperation of all physicians. It is believed that if these understood its value, all would seek its possession. To promote this understanding the Detroit Ophthalmological Club invited to its meeting May 3, the leading officials of Michigan medical societies and educational institutions. The following guests were present, took part in the discussions and endorsed the resolutions adopted, viz.: Dr. J. H. Carstens, president Michigan State Medical Society; Dr. Winfred Haughey, secretary-editor Michigan State Medical Society; Dr. Frank B. Tibbals, chairman medicolegal committee, Michigan State Medical Society; Dr. Charles T. McClintock, member of committee on organization, Michigan State Medical Society; Dr. Guy L. Kiefer, health officer of Detroit; Dr. W. C. Martindale, superintendent Detroit public schools; Dr. Gerald Edmonds, Honor, Mich., and Dr. W. C. Garvin, Millington, Mich., family physicians doing simple refracting. The chairman of the council of the Michigan State Medical Society, Dr. W. T. Dodge, sent a letter supporting the movement. Though unable to be present, like support was given by the following: Dr. Victor C. Vaughan, dean medical department Michigan University; Dr. H. O. Walker, secretary Detroit Medical College; Dr. Arthur D. Holmes, president of the Wayne County (Detroit) Medical Society.

The chairman of the meeting, Dr. Leartus Connor, opened the discussion by a paper on "The Economic Value of Family Physician Refracting." He called attention to the fact that in the United States there are about 180,000,000 human eyes; 135,000 doctors; 3,000 ophthalmologists. This averages 60,000 eyes for each ophthalmologist. As every eye over forty years of age needs refracting, most of them several times, and as very many eyes under forty need refracting, we have an explanation of the fact that the ophthalmologists never have been able to meet the refractive needs of all the people in the United States. Because the family physicians never have been trained to supply these needs, salesmen of spectacles entered the field, and gave such satisfaction as to secure large and increasing support. Farther, without realizing the nature of their action, a large number of educated physicians support and patronize the opticians. In the hope of encouraging family physician refracting, the paper pointed out the vast values inherent in its universal adoption; values to ophthalmology and ophthalmologists, to general medicine and the family doctor; to the profession as a whole, in strengthening its organization, in solving the optician problem and in providing such cooperation of ophthalmologist with family doctor that the 180,000,000 of human eyes in the United States may be cared for by educated physicians, obviating the existing necessity for laymen ophthalmologists.

It was urged that if these values were accepted by this conference the members could use their positions to stimulate others to comprehend the facts and master family physician refracting till its enormous values be harvested for both pro- [illegible] nd people.

[illegible] efracting was shown to be an art quite within the [illegible] ery medical student, without neglecting any other [illegible] s, and of practice by any doctor, not already over- [illegible] work.

[illegible] ed out that while ophthalmology has many [illegible] sts) it has few soldiers (*family physicians*) [illegible] so is impotent against the invasion of opti- [illegible] orde of laymen. But an equipment of the [illegible] vith simple refracting would transfer all [illegible] halmologic army who, in turn, would [illegible] e opticians could reach them.

Every member of the club and its guests took part in the discussion. Some detailed the steps by which they had cast aside the dominant practice and adopted the one presented. Many virile reasons were adduced for the change, and suggestions made for promoting the new doctrine.

Though lasting several hours, the conference never lagged but grew in interest from start to finish. Each saw in a new light a solution of present difficulties, vast benefits to the nation and increased honor to the profession.

Without neglecting aught of present good work, members of the Detroit Ophthalmological Club and its guests of May 3, 1910, adopted as their watchword "Family Physician Refracting" until every physician in the United States is equipped therefor.

Finally the following resolutions, on motion of Dr. Don M. Campbell, professor of ophthalmology, Detroit Medical College, were unanimously adopted by the club:

WHEREAS, Family physician refracting promotes the cooperation of family physician and ophthalmologist; provides physicians adequate for the people's refractive needs; enriches ophthalmology and ophthalmologists, general medicine and family doctor, strengthens medical organization and solves the optician problem.

Resolved, That the Detroit Ophthalmological Club endorses the action of the Section on Ophthalmology of the American Medical Association in promoting "family physician refracting," the action of the Michigan State Medical Society in seeking to qualify its members to meet the people's refractive needs; the action of the Kentucky State Medical Society endorsing the Michigan idea of family physician refracting; the action of the medical colleges in substituting "family physician ophthalmology" for "specialist ophthalmology," and the action of the state registration boards in Michigan, Vermont, Nebraska and Utah in requiring a "working knowledge of simple refracting."

Resolved, That the Detroit Ophthalmic Club urge other state boards of registration to require (1) for license, "family physician refracting," and (2) for the right to practice ophthalmology "A Comprehensive Laboratory and Clinical Study" after securing a license.

Resolved, That the Detroit Ophthalmic Club encourage family physicians to qualify for intelligent cooperation with ophthalmologists by equipping themselves for simple refracting.

It is suggested that much profit would result from other ophthalmic societies arranging similar conferences with officials of general or county medical societies, or even with groups of family doctors. Indeed, individual ophthalmologists might confer with little bands of family doctors and encourage them to master simple refraction, with the assurance of helpful results.

Finally, family physicians doing simple refracting might so confer with neighbors and local societies, that all become more competent for the refractive needs of their families.

91 Lafayette Boulevard.

POSTGRADUATE COURSE FOR COUNTY SOCIETIES

DR. JOHN H. BLACKBURN, DIRECTOR
BOWLING GREEN, KENTUCKY

[The Director will be glad to furnish further information and literature to any county society desiring to take up the course.]

Tenth Month—Third Weekly Meeting

EPILEPSY

ETIOLOGY: Heredity, organic and functional disorders in antecedents. Age, sex, preceding diseases, associated neuroses. Toxic agents, infections, syphilis, traumatism, reflex causes, mental strain.

PATHOLOGY: Varying changes found in different regions of brain, in neuralgia, in blood-vessels, in meninges.

SYMPTOM: Prodromes, character, time of onset. Auræ, motor, sensory, psychic, visceral, cerebral, etc. A. Complete convulsion, (a) tonic period, (b) clonic period, (c) period of stertor. *Modification* of each period. Status epilepticus. B. Incomplete attacks. Petit mal, vertiginous attacks, disturbance of consciousness, epilepsia procursiva, etc. C. Psychic equivalents of epileptic attack, automatism, etc. Post-paroxysmal conditions, tremors, paresis, loss of strength, diminished knee-jerks, petechiæ, headache, changes in urine, mental deterioration, etc.

DIAGNOSIS: Differentiate from hysteria, vertigos, toxic convulsions, organic brain lesions, transitory mania.

TREATMENT: Hygienic, dietetic. Physiological action of bromids, details of use in epilepsy. Use of other drugs. Patent medicines for "fits."

Medicolegal

Unlawful Practice of Medicine by a "D. S. T."

The Supreme Court of Indiana says, in Witty vs. State, 90 N. E. R. 627, that the party appealing, the defendant in the court below, who claimed to be a graduate of an institute of suggestive therapeutics, and in one of his advertisements appended the letters "D. S. T." to his name, was charged with practicing medicine without a license, in violation of the statute. The evidence established that he held himself out and advertised to the public by a sign in his office, and by publication in a local newspaper, that he was a "doctor," and capable and competent to successfully treat all forms of chronic diseases. He notified all persons, through the public press, that he was not only a "doctor," but that as such he was a specialist in the treatment of chronic diseases. He further advised them that he was capable of curing the many diseases mentioned in his advertisement without medicine or surgery, and that there were but few of the many diseases which did not yield to his drugless treatment.

The mere fact alone that in his practice he did not use drugs in any form whatever as a medicine to cure or heal the many diseases which he professed to successfully treat did not place him, in the eyes of the statute, within its meaning in the position of one not engaged in the practice of medicine. The term "doctor," as defined by the lexicographers, signifies or means, in one respect, a person who practices medicine. Consequently, when the defendant held himself out to the public, and advised them that he was a "doctor" located in the city; that he had certain office hours—he gave all persons to understand and be informed that he was at least engaged in the practice of healing or curing suffering humanity of diseases by some method or means adapted to that purpose, notwithstanding the fact he disclaimed the use of medicine of the character of drugs in his treatment of the diseases mentioned. He did not profess in his advertisement to be but a mere masseur engaged in giving massage treatment to all persons who might desire such, or who had been advised by their physician to take such treatment. He undertook to show by his advertisement that he was learned in his profession, and competent to diagnose diseases and prescribe the treatment necessary for a cure.

His counsel insisted that while it was true that he was shown to have had an office, that he advertised and held himself out as a doctor, "and was ready to and did administer to the wants of the sick, he did so exclusively by mental suggestion and by manual rubbing, and did not pretend to practice medicine in any shape or form." But the mere fact that he did not administer to his patients drugs in any form or manner, but confined his treatment to rubbing their afflicted parts, could not be held to exempt him from the provisions of the statute. If he, under the facts in this case, could be held as not coming within the provisions of the statute, then any person unlicensed to practice medicine might hold himself out to the public as a doctor, and treat all classes of diseases without administration of drugs, and not offend against the statute. Such a construction of the law would be inconsistent with its letter and spirit. The very object or purpose of the statute is to protect the sick and suffering and the public at large against the ignorant and unlearned by prohibiting them from holding themselves out to the world as doctors or physicians without having acquired any knowledge whatever of the human system, or the diseases and ailments with which it may be afflicted.

The defendant under the facts was properly convicted, and the judgment of conviction is therefore affirmed.

Operations from the Viewpoint of a Personal Injury Case

The Supreme Court of Iowa says, in White vs. Chicago & Northwestern Railway Co., 124 N. W. R. 309, that, of course, no one can be said to owe the duty of submitting to an operation, especially where the administration of an anesthetic is necessary in order that it be performed. No right is held more sacred, or is more carefully guarded by the common law, than is the right of every individual to the possession and control of his own person, free from all restraint or interference from others, unless by clear and unquestionable authority of law. As is well said by Judge Cooley: "The right to one's person may be said to be a right of complete immunity; to be let alone."

Whether an injured person shall submit to a further mutilation of his person is essentially a matter of personal choice. This is necessarily so, for experience has demonstrated that every operation is performed with some risk. But when pain may be obviated, and the condition of the injured member improved, by an operation without injury and at small expense and slight inconvenience, the person injured ought not to be recompensed on the theory that he will not avail himself of the benefits of modern surgery. Nor, on the other hand, is compensation to be limited to the reasonable cost of surgery as though the injured person were a chattel being put in state of repair. The feasibility of an operation calculated to obviate pain and improve conditions is to be considered by the jury, not owing to any duty of the injured party to submit his person to the surgeon's knife, but as bearing on the nature and extent of the injury and the probable consequences when accorded such treatment as ordinary prudence shall dictate.

It was requested that the jury be instructed in this case that if they found from the evidence that the injured man's fingers, at the place of amputation, still caused him pain, and that such pain could be obviated by a new amputation, at small expense, and without serious danger to him, then it would be his duty to have such new amputation, and he would in no event be entitled to recover for any pain or suffering that such new amputation would prevent. The instruction was refused, and it was not without fault, but the attention of the jury might well have been directed to the feasibility and probable effect of the operation as bearing on the amount of damages to be allowed.

6 What the Fight Against Tuberculosis has Accomplished. S. J. Maher, New Haven, Conn.

1. **Newer Conceptions of Myocardial Disease.**—To the classification of myocardial disease presented several years ago, Satterthwaite adds another form—atrophy of the heart, which is, however, very rare. His classification is as follows: (1) Acute parenchymatous myocarditis; (2) acute diffuse myocarditis, including the tuberculous, syphilitic and suppurative forms; (3) chronic myocarditis; (4) the fat heart; (5) the fatty heart; (6) hypertrophies, and (7) atrophies. Neither dilatation nor spasm is included in the table. Satterthwaite says that they are incidents which occur at times in any of the varieties mentioned, and cannot, therefore, be considered separately. He discusses the pathology and diagnosis of the various forms and their treatment.

11 Proctoclysis. P. W. Harrison, Boston.

7. Circulatory Failure in Acute Infections of Children.—Critical clinical observation and animal experimentation, says Howland, are in accord in referring the cause of circulatory disturbance in acute infections to a failure and final collapse of the vasomotor center. There is also almost complete agreement obtained by animal experiments and by modern methods of determining the human circulatory capacity as to the drugs and methods most useful in this circulatory disturbance. He says that from the knowledge at present available it seems that the continuous use of cold air, the use of caffein and camphor reinforced by digitalis, with infusions of salt solution and the careful administration, not too often repeated, of adrenalin, are our best methods to combat this dangerous condition.

10. Spirochæta Pallida in Umbilical Cord of the New-Born Infant.—Emmons studied the cords in 30 cases suggestive of syphilis. When the child was born alive, the portion of the cord immediately adjoining the ligature was studied, and in stillbirth cases the portion between the ligature and the abdomen. Whenever possible, autopsy was done, and in each case the routine microscopic examination of the placenta gave a clue as to the probable diagnosis. The tissue was imbedded in paraffin and the sections stained by the method of Levaditi. Whenever the livers from the corresponding children were obtainable, they were imbedded at the same time, so that sections could be compared with those of the cord. When positive results were obtained, the liver sections showed the abundant presence of a well-stained spirochete, and in such cases numerous sections of cord were studied and a negative report registered only after a most prolonged and careful search.

From this study, Emmons draws the following conclusions:

1. *Spirochæta pallida* is rarely found in the cords of the syphilitic new-born infants. When positive results are obtained, they are present in considerable abundance in the muscularis of the umbilical vein in sections taken from the neighborhood of the umbilicus.

2. A large proportion of syphilitic new-born infants, as shown by microscopic examination of the placenta, as well as by characteristic autopsy findings with spirochetes demonstrable in the liver, show that spirochetes could not be found in the cord even after extensive search. Accordingly a negative diagnosis cannot be made by this procedure alone.

3. Occasionally the search for spirochetes in the cord may be of positive value as a clinical test. But the much greater frequency of negative findings hardly justifies its adoption as a routine procedure.

26. Gastric Crises of Tabes.—A woman, aged 49, complained of severe pains in the back and stomach, and also of headache. Except for vague "rheumatic" pains for some 10 years she suffered from no disease until the present trouble began. About eight years ago she began to have attacks of pain in the back, indigestion and pains in the joints, especially in the shoulders and knees. The pain in the small of the back was tolerably severe, and was sometimes associated with nausea. She has suffered much from headache, frontal and occipital, and she thinks that her eyesight has failed during the last few years. The individual attacks begin with a feeling of a lump in the throat which cannot be swallowed (globus?). Vomiting soon comes on, so that nothing can be retained in the stomach, and she has extreme pain in the back and abdomen and complains of sensitiveness of the skin of the trunk. The pain is so severe that she usually weeps violently and tosses about in bed, grinding her teeth. She has never lost consciousness in an attack, nor has there been any disturbance of the sphincters. Her mind seems clear during the attacks. Since about a year ago there have been nearly two attacks a week, each lasting from a few hours to three days. She has noticed palpitation of the heart during some of the attacks. In the crises from which this woman suffered the pain was situated in the upper abdomen and radiated into the back. The pain was accompanied by paroxysmal arteriospasm, with great elevation of the maximal arterial pressure. That the hypertension depended on the arteriospasm was evident from the effect of amyl nitrite, which reduced the maximal pressure promptly to 90 mm. Hg., though as soon as the effects of the nitrite had worn off the hypertension reappeared.

27. Typhoid in Children.—There were 65 deaths, a mortality rate of 11.8 per cent. in this series reported by Adams. Taking the periods separately, we see the greatest reduction in the last decade and a half, which he thinks is unquestionably due to the methods of treatment employed. From 1892, the beginning of the third decade, to 1898, inclusive, the treatment followed was hydrotherapy, antiseptic and antiperiodic. During this time 88 patients were treated; 10 died, a mortality of 11.36 per cent. At the beginning of 1899 the purely hydrotherapeutic treatment was begun and has been strictly followed throughout the remainder of the decade, with the result that of the 164 patients then treated, 18 died, a death rate of 10.97 per cent. Four patients of the last series died of pulmonary tuberculosis either during or directly following a typical course of typhoid. Excluding them from the mortality list, the death rate will be 8.54 per cent.

Some slight changes in treatment have been instituted during the last half decade. The diet was augmented in nutritive value by the addition of cereals, eggs and bread to the prescribed routine of milk and broths. The patient's ability to digest such "soft food" was carefully watched and only two or three instances were recorded in which the semisolid food had to be discontinued. By adopting this method, Adams says that most of the heart-rending scenes of the sick-room will be avoided. The otherwise patient child no longer begs and cries for "something to eat;" there is no longer progressive emaciation until the little skeleton is covered by loose skin hanging in folds; relapses become less frequent; convalescence is shortened, and complete recovery replaces prolonged invalidism.

31. Helminthiasis in Children.—Twelve of 30 children who suffered from unexplained nervous or gastrointestinal symptoms were found by Schloss to harbor intestinal worms. Consecutive examinations of 280 children showed that 80 (28.57 per cent.) harbored intestinal worms; 5 of the children harbored 2 species of parasite, giving a total of 85 infections. Thirty-one (11.07 per cent.) of the children harbored *Trichuris trichiura*, 23 (8.21 per cent. harbored *Oxyuris vermicularis*, 20 (7.14 per cent.) harbored *Hymenolepis nana*, 6 (2.14 per cent.) were infected with *Ascaris lumbricoides*, and 5 (1.78 per cent.) with *Tænia saginata*. Only 1 of 33 children infected with *Trichuris trichiura* (from both groups of examinations) suffered from symptoms. Thirty-five of the 51 children infected with the other parasites (from the consecutive examinations) suffered from symptoms. The eosinophil blood cells were not increased in cases infected with *Trichuris trichiura*.

34. Wassermann and Noguchi Fixation Tests.—It is claimed by Fox that a positive Wassermann reaction is frequently obtained in cases of leprosy giving no history or symptoms whatever of syphilis. The reaction is at times very strong, inhibition of hemolysis being complete. It occurs chiefly in the tuberculous and mixed forms of the disease, especially in advanced and active cases. In the cases of the maculoanesthetic and purely trophic type the reaction is generally negative.

35. **Effect of Tuberculosis on Intrathoracic Relations.**—Francine's report deals with the changes brought about in intrathoracic relations as shown by skiagrams of 60 patients with pulmonary tuberculosis, studied clinically before and after the taking of the skiagrams. Frequently in advanced pulmonary tuberculosis the aorta is displaced as well as the heart and in the same direction, usually to the right. In the present series, many of which were advanced or far advanced cases, the heart in the majority of instances was not displaced. Absence of displacement is much more common, in fact, almost the rule, in acute infiltrations and consolidations, before fibrosis and contraction have taken place. In many instances, even when the lesions were widespread and often destructive, the heart was not displaced. When the pulmonary lesions are of fairly symmetrical character on both sides, the heart is more commonly displaced to the right than to the left. In these cases there is usually evidence to show that the primary and older lesion is on the right. When the lesion is more extensive on the left the heart is not so regularly displaced nor to the same extent, as in corresponding right-sided lesions. Rarely the fibrosis of the lungs and pleura may be so great or of sufficient density to obliterate the boundaries of the heart. In many cases the skiagrams show an interesting feature which is not demonstrable clinically, namely, that during systole of the heart there is an area between the lower boundary of the heart and the diaphragm of about the extent of one centimeter, which distinctly transmits the *x*-rays. The limits or extent of the cardiac excursion may also be seen in many cases. In four cases, distinct pericardial adhesions could be seen.

The heart appeared normal in size, both in the skiagrams and to physical examination in all the cases, with four exceptions. In three of these the enlargement was practically confined to the right side, and the lungs were markedly emphysematous. In one case there was a general hypertrophy. There was no evidence of an organic valvular lesion in the series, though in some cases soft systolic murmurs were audible in the mitral and pulmonary areas. The skiagrams were taken under full inspiration. In 29 cases (48.33 per cent.) the diaphragm was unaffected by the pulmonary lesion. The diaphragm was affected in this series in 51.66 per cent. of the cases. In every case in which the heart was displaced the diaphragm was elevated on the side toward the displacement, and in the cases in which the heart assumed the anteroposterior position the diaphragm was elevated on both sides. The diaphragm was affected in 9 cases in which the position of the heart was normal.

In every case in this series the cervical glands were enlarged to palpation. In 51.66 per cent. of the cases enlarged glands could be seen in the plates. With the exception of about 6 cases all those in which enlarged glands were visible, were either early or moderately advanced, without the breaking down of tissue; while in the majority of the advanced cases the glands did not show. It would appear as if there were two explanations for the absence of glands in the majority of plates in which they were not visible, namely, that their presence was concealed by the area of involvement, or what appears more likely that with the advance of the disease the glands had softened or broken down and so failed to give rise to a shadow. There were usually only 3 or 4 glands noted in any one plate, and in a number of instances they appeared to be calcified.

The presence of calcareous infiltration in the costal cartilages was noted in only 8 cases. It was usually confined to the costal cartilage of the first rib, though in one instance it involved all the cartilages. In the majority of advanced cases the involvement was of sufficient density and extent to have concealed the presence of calcification in the cartilages of the first rib, but there was no evidence of calcification in the costal cartilages which could be properly studied.

51. **History and Occurrence of Pneumonia.**—All available statistics, says Lewis, point to the fact that pneumonia is increasing. Especially does this seem to be so in certain localities, as, for instance, in Chicago. During the last 40 years the mortality from pneumonia has increased from 4.4 to 19.95 per 10,000 inhabitants. The last U. S. Census shows that pneumonia, next to tuberculosis is responsible for a larger number of deaths each year than any other disease. Of 12,098 cases, 8,881, or 73.41 per cent., occurred in males, and 3,217, or 26.59 per cent., in females. Among 10,159 cases, the disease terminated by crises in 5,397, or 53.1 per cent.; in 1,042 cases, 21.7 per cent., the crises occurred on the seventh day; in 625 cases from the tenth to the seventeenth day.

Among 2,613 cases death occurred as follows: Before the fourth day, 161 cases; fourth to twelfth day, 1,483; twelfth to eighteenth day, 403 cases. The greatest number of deaths occurred on the seventh day, 230.

54. **Pneumonia in Children.**—The one drug recommended by Kerr in bronchopneumonia is belladonna, but to be effective, he says, it must be given in doses large enough to cause flushing of the face; it may be continued for the first few days. Small doses are of no value and its protracted use is not indicated. There must be secured for the child (1) the best hygienic surroundings possible; (2) a diet reduced but of such quality as properly to support the system; (3) free administration of water; (4) regularity of the bowel function; (5) abundance of fresh cool air day and night; (6) strict cleanliness of the body, and particularly the nose and mouth; (7) as perfect physical and mental quietude as possible. The cautious use of the internal emetics is sometimes attended with benefit, and while an initial vomiting may prove beneficial in clearing away the bronchial mucus, this method must not be persisted

in. Counterirritation with mustard paste is valuable, and it is not wise to wait until pulmonary collapse is suspected, for used early it gives relief from the dyspnea and cough. Everything that weakens should be avoided; everything that strengthens encouraged. Stimulation is not alone wise, but absolutely necessary after the first few days. Delay until the necessity is present means much lost ground, for everyone of these patients needs stimulation practically throughout. Kerr's preference is for a combination of small doses of camphor and whisky; the camphor being given in sweet almond oil (¼ grain to 5 drops) and the whisky well diluted with water. Tonics should be given just as early as possible, for delay in this matter, as in the case of stimulants, may mean lost ground.

58. **Vaccines in Pneumonia.**—Stewart holds that the pathologic conditions resulting from an acute pneumococcic infection can be relieved, removed or modified, by injecting subcutaneously killed bacteria of the species causing the diseased condition.

72. **Substernal Respiratory Squeal.**—The sound described by Curtin was discovered accidentally. It is the "*bruit du diable,*" or venous hum of the veins of the neck in extreme anemia, which hum it seems to resemble more than any other sound. It resembles to some extent the hissing squeal or singing of a boiling tea-kettle. It is more like a shrill musical whistling than a humming sound. It is remittent when strong, is loudest on inspiration, and becomes faint or is lost on expiration.

The continuousness of this sound, says Curtin, shows that it is not produced at the aortic, pulmonary or tricuspid orifice; otherwise it would cease when the blood current is stopped by the shutting of the valves at these orifices. The only places in the heart at which there could be a continuous sound, such as the one described, would be in the blood flowing into the right or left auricle, and these two places in the heart are the only ones where the respiration has a perceptible modifying influence on the flow of blood; but, again, the shutting of the mitral and tricuspid valves has a modifying influence on the current, which would be perceptible in an abnormal sound connected with it.

The point of greatest intensity of the sound is a little to the left of the median line of the sternum at or just below the second cartilage. Curtin therefore locates the sound at or near the upper part of the left auricle where the pulmonary veins empty into it. The sound is louder, stronger and coarser (indicating a larger vessel and a more active flow of the blood) than the sound heard at the base of the neck, when the jugular is pressed with the stethoscope; but it is of the same general character. Its location under the sternum places it beyond the reach of any pressure. It is not influenced by the action of the heart; that is, one cannot find any change in the sound with the systole or diastole. During inspiration there is a marked change. Just at the commencement of inspiration the sound becomes gradually louder and more pronounced until the beginning of expiration, when it begins to diminish. In some cases it was not audible after the commencement of the act of expiration.

98 Dysmenorrhea of Uterine Origin. S. J. McMamara, Brooklyn.

94. **Transfusion of Blood.**—Direct transfusion, according to Hempelmann, is indicated in postoperative hemorrhage, hemorrhage of typhoid, gastric ulcer, purpura, hemophilia, hemorrhagic disease of the new-born infant, illuminating gas poisoning, and possibly in pernicious anemia. It has been found useless in cancer, Hodgkins' disease, uremia, leukemia and in infectious diseases.

97. **Standardization of Disinfectants.**—Gradwohl endorses the Rideal-Walker method of standardizing disinfectants which is now used and insisted on in Great Britain and throughout Europe as an official standard, bearing the endorsement of the Admiralty, War Office and Local Government Boards of Great Britain. He urges that local, state and government boards in the United States should adopt it and require all manufacturers of disinfectant solutions to label their products clearly to show the carbolic-acid coefficient. If manufacturers are honest in their claims, they should be willing and eager to have official bacteriologic checking of their products with the Rideal-Walker technic. Physicians and laymen should likewise insist on manufacturers showing the carbolic-acid coefficient of their respective products when they desire patronage. In this way the honest manufacturer may make his dishonest competitor come out into the light and be exposed. Only those who are making false claims will oppose this procedure. It is fair to the maker, to the consumer and to the bacteriologists.

108. **Improved Method of Preparing Catgut Ligatures.**—McDonald has adopted the following method of preparing catgut: (1) Iodin 4 per cent. in acetone, 8 days; (2) wash in acetone, 4 days; (3) preserving solution, acetone, 85 per cent.; Columbian spirits, 10 per cent.; glycerin, 5 per cent. The glycerin should first be dissolved in the alcohol and then added to the acetone, as *acetone itself is not a solvent of* glycerin. This method is said to possess the following advantages: The solutions are fat solvents and antiseptics; the iodin is used in greater strength than in Claudius' method and it impregnates the gut so that the ligatures are black and well saturated with iodin when they are placed in the clear acetone solution. The pure acetone abstracts the excess of iodin from the gut, leaving the gut clear and white. The preserving solution of acetone, alcohol and glycerin completes the bleaching, and at the same time softens the gut, which is not much softened by the pure acetone. The latter, however, does not harden the gut, but abstracts the water from it and leaves it of the same flexibility as gut that has been preserved in chloroform, as in the well-known commercial process. The addition of the glycerin and alcohol to the acetone in the preserving solution is sufficient in amount to soften the catgut; at the same time the dehydrating power of the acetone prevents the gut from swelling up, as it does when it is placed in alcohol solution. Acetone itself, he states, is also a very strong antiseptic.

133. **Action of Preparations of Tuberculous Lymph Glands on Experimental Tuberculosis.**—The experiments conducted by Trudeau and Krause fall into four series; two with homologous gland extracts, and two with extracts of human lymph glands. They found that guinea-pigs treated with material from homologous tuberculous glands are not immunized against the development or spread of experimental tuberculous injection. The gland material in this series probably contained tubercle bacilli. Guinea-pigs treated with filtered extract of homologous tuberculous glands do not resist experimental tuberculosis. This extract was used in a comparatively fresh condition. The experiment was not regarded as a fair test because of the high dilution of the extract and the small number of doses that the animals receive. Guinea-pigs treated with filtered extract of tuberculous human glands showed an apparent resistance to the spread of tuberculous infection. This resistance was probably only apparent. The extract was from glands in various stages of the disease—hyperplastic and necrotic. Treatment was fairly thorough, and the use of the extract was begun immediately after preparation and continued for 6 weeks. Guinea-pigs treated more thoroughly with filtered extract of tuberculous human glands acquired no immunity against infection from tuberculosis or its development. The extract was from glands that showed various grades of disease, from early to advanced. It was concentrated and its use was begun three months after its preparation.

155 *Hemolysis *in Vitro* and *in Vivo* as a Means of Diagnosis of Carcinoma. A. Krida, Schenectady, N. Y.

155. **Hemolysis in Diagnosis of Carcinoma.**—Of a total of 1,812 observations reported by 10 different workers, 472 cases were carcinoma, and of these 317, or 67 per cent., gave positive hemolytic reactions; 79 were benign tumors, of which 1 or 1.25 per cent. were positive; 507 observations were made in a variety of diseases, 74, or 15 per cent., of which presented positive reaction; 509 observations were made on normal individuals; 14, or 2.6 per cent., were positive. In 40 postoperative carcinoma cases without clinical recurrence. the reaction was uniformly negative. One hundred and eighty-eight tests were performed on tuberculous patients; of these, 82, or 44 per cent., presented Crile's "reverse" hemolysis. Krida has made 76 tests. In 12 cases of carcinoma, the reaction was positive in 9, or 75 per cent. In 4 cases of carcinoma without clinical recurrence the reaction was uniformly negative. In 23 cases of a variety of diseases, 1, or 4 per cent. (chronic ulcers), presented a positive reaction. Of 25 clinically well patients, 2, or 8 per cent., responded positively to the reaction. In a certain small number of cases not clinically carcinomatous, a positive

reaction was obtained. There were in all 5 such cases, in all of which Krida applied a second test 2 or 3 days after the first. The second test was positive in 3 of the cases; one of these was a case of chronic ulcers; 2 individuals were normal. In the remaining 2 patients, clinically well, the test proved negative. The hemolytic reaction occurs in so great a percentage of carcinoma cases and in so small a percentage of normal individuals and patients with other diseases, which conditions can usually be differentiated, as to make it of material diagnostic assistance in doubtful cases, especially in doubtful cases of carcinoma of the gastro-intestinal tract. Especially as it is so simple of application, Krida holds that it should be performed in all suspected carcinoma cases. The "*in vivo*" or "skin" reaction, because of its better scientific basis, and because it is technically less difficult and time-consuming, Krida regards as the clinical method of choice.

161. **Effects of Distilled Water and of Various Solutions on Muscles.**—Meigs' investigation shows that the sarcostyles of the striated muscles of frogs are so constructed that any increase in their volume brings about, as a necessary mechanical result, a decrease in their length. All forms of muscle rigor are due to the swelling produced by an accumulation of acid within the muscle. The removal of rigor with salt solution, and particularly by salt solutions which contain small quantities of sodium bicarbonate, is explained by the removal of the acid reaction of the muscle. The conclusion of McDougall seems to be correct, that the contraction of striated muscle is the result of the swelling of the sarcostyle, which in its turn is brought about by the examination within them of the minute quantities of lactic acid.

4 Meningitis in Children. G. Rankin.
5 An Immunizing Subinfection in Scarlatina. A. D. Edwards.
6 *Results of Thyroid Treatment in Infantile Wasting. J. W. Simpson.

1. **Less Common Aspects of Pneumonia.**—Oliver has not seen any striking result follow the use of pneumococcus serum, nor can he recall a case of pneumonia having been saved by the inhalation of oxygen. Strychnin and digitalis have given him the best results. With pneumonia, he says, as with many other illnesses, it is not the disease solely that requires to be treated, but the patient with the disease.

2. **Pneumonia in Childhood.**—Whipham emphasizes the fact that while bronchopneumonia is the more frequent type in early life, the lobar variety is commoner than is often supposed. Thus among 150 of his own cases he found that 65, or 43.3 per cent., were of the lobar type. The chief clinical distinction between the two are these: (1) lobar pneumonia is almost always primary, while bronchopneumonia is very frequently secondary; (2) the onset of lobar pneumonia is sudden and the symptoms are well-marked, whereas bronchopneumonia begins insidiously as a rule; (3) the temperature in the lobar form tends to be more uniformly high and to end by crisis, whereas in the other the course of the fever is prolonged and irregular and rarely ends abruptly; (4) lobar pneumonia usually affects a localized area of one lung, at any rate to begin with, while bronchopneumonia is bilateral and more extensive; (5) bronchopneumonia tends to occur at a slightly earlier stage than lobar. Lobar pneumonia, according to Whipham's experience, is most frequent during the second, third and fourth years, 56.9 per cent. of his cases occurring during those years, whereas bronchopneumonia chiefly occurs during the first three years of life, as many as 70.6 per cent. of his cases being found in infants under 4 years of age. In lobar pneumonia one or other of the bases is most frequently attacked, most commonly the left, but in children it is not unusual for the apex of the lung to be affected. It is a remarkable fact that if one apex is involved—primarily and not as the result of the extension of the disease from the lower lobes—it is practically always the right apex which is attacked.

3. **Hospital Infection of Tuberculosis.**—It would appear from the experience of the Mount Vernon Staff, of which Squire is a member, that the risk of infection with tuberculosis in a special chest hospital is very small, and is apparently little, if at all, greater than in a general hospital. It is, perhaps, doubtful if there is any greater risk to the workers in any well-ordered hospital than among the general mass of town dwellers of similar social position. Infection with tuberculosis does occasionally occur as a result of the duties of a nurse, but probably not more frequently among the nurses in a hospital for consumptives than among the general body of nurses. Every occupation has its special risks, and the possibility of infection is one which members of the medical and nursing profession accept as a matter of course. The risk of tuberculous infection, even in a hospital for consumptives, appears to constitute a very slight danger.

6. **Thyroid Treatment in Infantile Wasting.**—Out of a total of 80 patients treated with thyroid by Simpson, 72 were infants under 9 months, and their history was usually one simply of wasting. In the 8 over this age the wasting had supervened after some acute disease. Out of the total (80), 12 died and 5 did not return to the hospital after treatment had been carried on for 2 or 3 weeks. In the 12 cases which ended fatally, 2 children were extremely ill. In both these children the weight was 4 pounds, and both showed evidence of failing

circulation, edema of legs, etc. One died 2 days, and the other 4 days, after being first seen. Two others suffered from marasmus due to congenital syphilis; of the other 8 who died 1 improved for some little time, but eventually died of tuberculous meningitis, 2 were from the country and were only seen a few times, while the remaining 5 did not react to treatment in the slightest degree. The remaining 63, however, all did well. No doubt a number of those infants would eventually have improved on dieting alone, but the fact remains that they failed to put on weight for the first 2 or 3 weeks on such treatment, and that on the addition of thyroid (the same dieting being continued) a number of them at once increased rapidly in weight, while some who remained stationary for a week or two showed beneficial results after that time. Five of Simpson's patients were syphilitic, and wasting was a marked symptom. Mercury was at first given without any effect on the weight, then alone with mercury, thyroid was administered. The result was that 3 out of the 5 infants began to gain and eventually recovered. The other 2 (already noted) did not react at all and death ensued. Of 8 children over 9 months old who were suffering from malnutrition, following an attack of an acute disease, 6 improved on thyroid treatment, 1 died of tuberculous meningitis, and 1 was lost sight of. Simpson has only mentioned 8 cases of older children, but in the last 6 months he has used thyroid frequently for such children suffering from debility after such acute diseases as pneumonia, measles, and whooping-cough. The results have been favorable, except in those cases which proved to be tuberculous; in such cases thyroid treatment would seem to be contraindicated. In the treatment of children under 9 months, Simpson begins with ⅓ grain thyroideum siccum once daily. In older children, he goes up to 1 grain once daily, according to the age of the child. In the giving of thyroid it is advisable, he says, to test the feces to see whether they are acid or alkaline. In 2 cases in which thyroid appeared to produce no good results, he found that the stools were very markedly acid. Sodium bicarbonate was then given 3 times a day, and shortly afterward both children began to improve.

23 Gonorrheal Arthritis Treated by Vaccine Therapy. W. R. Jack.
24 Cases Treated by Injections of Bacterial Vaccines. J. Miller.
25 *Case of Merycism. J. Lindsay.

22. Gastric Carcinoma with Bone Metastases.—In this case the emaciation of the patient and the melena, with a history of occasional dyspepsia, and on one or two occasions of vomiting of brownish material, were sufficient to arouse suspicion. Still the gastric symptoms were not clamant, and on examination of the abdomen nothing abnormal could be made out beyond some distention. No enlarged glands could be felt. The patient's general condition vetoed gastric analysis. The only complaint was of pains in the back and thighs. There was some tenderness in the sacral region and over the left thigh. Any movement of the body or lower limbs appeared to cause great pain. The appearance of the patient was that of a woman who had been losing blood and weight for some time, and her emaciation during her hospital residence was rapid. Carcinoma of the stomach seemed a probable diagnosis. The blood picture was foreign to that usually seen in the anemia of cancer of the stomach, and was suggestive of pernicious anemia. Postmortem showed the tumor of the stomach to be a carcinoma. The secondary growths in the kidney, bone marrow and lymphatic glands showed a tendency to atrophy of the epithelial element and development of fibrous stroma. The white tissue filling the ribs and cancellous heads of the long bones proved also to be tumor. Some parts of the tumor in the bones showed young cellular carcinomatous tissue, but the greater part was more or less degenerated, showing shrunken cells, and a large amount of fibrous stroma. Many large areas consisted of fibrous tissue only, but the nature of this was easily made out by tracing the stages in the transformation between it and the young tumors. Most of the red areas in the ribs were found to represent hemorrhage, but a few were red marrow. The head of the femur likewise contained much more tumor than red marrow; and the vertebral bodies showed a large proportion of marrow, but on the whole, rather more tumor. The red marrow had, in fact, almost entirely disappeared from its normal sites.

25. Merycism.—Lindsay's patient, aged 56, had regurgitated and remasticated his food since boyhood. He began his working life as a baker, and was the fourth generation of his family to follow that occupation. He suggested that the hurried meals and irregular hours attaching to the work of a baker in the country may have had something to do with the habit; but he admits that it had begun while he was still a boy at school. Haste in eating is, however, associated with regurgitation; for the solid portions of a meal that has been imperfectly masticated usually return to the mouth, sometimes half an hour, sometimes three or four hours after being first swallowed. The regurgitation is altogether involuntary, and when his appetite is poor it may not occur for a week at a time. It is not preceded by any feeling of discomfort or other evidence of indigestion. The remastication is pleasurable, the food, he says, being softer and sweeter than when first taken.

35. New Method of Ether Anesthesia.—The method used by Hornabrook is one of open ethyl chlorid followed by open ether. The mask used is an ordinary wire frame, covered with one layer only of very thin flannel. The mask is placed on the patient's face, and the patient told to breathe quietly and naturally; that there will be no unpleasant sensation of suffocation, and that after a few drops of the anesthetic have been placed on the mask a pleasant floating sensation will come over him. The ethyl chlorid is dropped, not sprayed on to the mask. If ethyl chlorid is sprayed on, it freezes on the mask, does not act so well on the patient, and more is used than necessary; the drops should be rapid and spread over a wide area: from 3 to 8 c.c. are generally required. Hornabrook has never seen any sign of collapse under this open ethyl chlorid method, and in one case 25 c.c. were dropped on the mask to try its effect on the patient. The patient passes under the anesthetic rapidly and pleasantly, without any feeling of suffocation or discomfort. After 5 c.c. of ethyl chlorid have been dropped on the mask, a few minims of ether are dropped—that is in ordinary women or anemic men; if the patient is full-blooded or alcoholic, it is better to pass from ethyl chlorid to chloroform before going on with the ether. As a rule not more than 30 minims at the most of chloroform are necessary before muscular relaxation is obtained, and ether can then be substituted. Muscular relaxation when once obtained does not return to rigidity except in very rare instances, and even if it does, a few drops of chloroform will reduce it. The time taken to place the patient under anesthesia ready for the knife is from three to five minutes from the first drops of ethyl chlorid. A patient can be maintained under this open ether for any length of time. There is practically no secretion of mucus, so that the air passages remain clear; the breathing is quiet and easy; the color of the patient remains excellent, it being very rare to see blueness, even in prolonged cases; the patient recovers from the anesthetic very quickly; the pupils should be maintained very active and of medium size throughout; and the upper lid should remain elastic to the touch. Care must be taken that the anesthetist has two masks, for after a time a coating of moisture forms on the under surface of the flannel and this acts as a barrier between the patient and the ether, so that the patient gets none or very little ether in spite of the quantity poured on the mask, and the patient then commences to come out. The mask should be changed for a dry one before this happens, and the old one wiped free from moisture to be used again later; it may be necessary in a prolonged operation to change the mask more than once. The amount of ether poured on the mask varies with the length of the operation, but, speaking generally, about 20 minims every half minute, the quantity used is from 4 to 5 ounces in the first hour and less in the second. The state of anesthesia induced is light, the muscular relaxation good, and even should there be rigidity, as may be the case, it is easily overcome with a few drops of chloroform. The patient can be brought out of the anesthesia very easily and rapidly, in fact, in many respects it resembles sleep rather than deep narcosis of an anesthetic, the shock of even a very prolonged and severe operation is well-borne, the patient being in no way depressed as he would have been under chloroform, or irritated by concentrated ether vapor and excessive secretions of mucus as under a closed method.

52 *Pathogenesis of Renal Hematuria.* B. Motz.
53 Case of Hydronephrosis from Obstruction of Ureter with a Stone Afterward Partially Absorbed. E. Hauch and J. E. Lohse.
54 Pathogenic Rôle of Abnormal Renal Arteries. A. Pousson.

49. Superiority of Pyelotomy.—Périneau advocates this operation as no more serious than nephrotomy, while it spares the kidney parenchyma and there is less danger of hemorrhage and tendency to a fistula later. Calculi are more frequently found in the renal pelvis and the pyelotomy permits retrograde probing of the upper ureter to determine the presence of other stones. He declares that, accompanied by Roentgen-ray examination, pyelotomy is destined to take the first place in operations for calculi in the calices, pelvis and upper ureter. His article is based on 103 operations of the kind done at the Lariboisière hospital.

52. Hematuria.—Motz ascribes renal hemorrhage to some inflammatory lesion rather than to mere congestion.

68 *Hemorrhage in Suprarenals Due to Chloroform. M. Savariaud, *Pellot* and Tinel.

68. Hemorrhage in Suprarenals After Chloroform Anesthesia.—The patient was a boy of 8 requiring a 20 minute operation to correct eventration 18 months after appendicectomy. The operation and anesthetization proceeded smoothly but soon afterward the child became very restless and signs of acute intoxication became apparent—green diarrhea, vomiting, profound depression, drop in the blood pressure, extreme tachycardia and tendency to erythema; the little patient died in six days, the syndrome in general suggesting acute suprarenal insufficiency of a pseudoperitonitic form. All the organs were found congested but the suprarenals had been the seat of extensive hemorrhage.

77 Serotherapy of and Vaccination Against Acute Articular Rheumatism. G. Rosenthal.

72. **Albumin Reaction in Sputum.**—Roger and Valensi state that sputum from the tuberculous always contains more or less albumin, while a mild, simple bronchitis or pulmonary emphysema does not add this albuminous element to the sputum. Its presence indicates a deeper inflammation or exudation. The absence of albumin thus permits tuberculosis to be excluded; its presence has less decisive value as there are a number of processes that may cause albumin to appear in the sputum. They relate experiences to show the simplicity and ease of the albumin sputum test. The sputum is collected in a dry recipient, as free from saliva as possible, never using sputum containing blood. The sputum must be fresh, as decomposition splits the mucin and liberates albumin. It is mixed with an equal amount of water, stirred and a few drops of acetic acid added to coagulate the mucus. The mixture is then filtered through ordinary filtering paper and heated to coagulate the albumin; a little sea salt has to be added to ensure the coagulation of the albumin in the absence of electrolytes; other means can be used to test for the presence of albumin. In 64 cases of tuberculosis and in 20 reported by Oddo the findings were almost invariably positive. This was particularly important in 31 cases in which the diagnosis was wavering and the finding of albumin in the sputum aided in differentiating the disease; the diagnosis was confirmed by the course of the cases later. In one case the test was negative as also the tuberculin test until a large dose of tuberculin was given when there was a febrile reaction and albumin was found in the sputum, but as soon as the reaction had subsided all the findings were negative again and the patient has been in good health since. This case demonstrates the value of the albumin reaction, as negative findings, even with tuberculous infection, show that the process has been arrested.

82 *Continuous Stream of Oxygen in the Treatment of Abdominal Disease. (De l'emploi du courant continu d'oxygène en chirurgie abdominale.) T. Weiss and L. Sencert.
83 *So-Called Idiopathic Hematuria. (Sur les hématuries dites essentielles.) R. Robinson and J. Jacoulet.
84 *Ischemic Paralysis and Contracture of Volkmann. (Quelques notions fondamentales sur la retraction musculaire ischémique de Volkmann.) A. Binet. Commenced in No. 3.
85 *Paralysis with Dislocation of the Shoulder. (Les paralysies dans les luxations de l'épaule.) P. Delbet and A. Cauchoix.

80. **Dry Caries of the Hip Joint.**—The authors state that this special form of tuberculous arthritis in the hip is analogous to that known as Volkmann's dry caries of the shoulder. The lesions have been described under the heading of juvenile deforming osteoarthritis or torpid or atypical coxalgia. Pain, functional impotence and muscular contracture are the main features at first; the absence of fungous granulations and of effusion is also characteristic. The affection tends to a spontaneous cure by ankylosis, the course lasting two years at least. In three of the ten cases mentioned operative treatment was applied on a mistaken diagnosis, but continuous extension with plaster immobilization to favor ankylosis in a good position is the treatment recommended. The article is accompanied by the bibliography.

82. **Continuous Current of Oxygen in Treatment of Abdominal Disease.**—Weiss and Sencert discuss the value and the mode of action of the application of a constant stream of oxygen in the treatment of surgical abdominal affections. The hundreds of cases in which the method has been applied abundantly confirm the advantages of this method, which is based on the biologic properties of oxygen, the results of experimental research and histologic examination demonstrating that in the presence of microbes the oxygen promotes the diapedesis of white corpuscles, augments their phagocytic properties, and stimulates the vitality of the reparative elements. They have applied the method in gaseous gangrene, suppurating arthritis, purulent pleurisy, diffuse phlegmon and osteomyelitis and chronic suppuration with compound fractures—the results were always good but it was after operations that it proved most beneficial. They review their experience in detail, reiterating that oxygen injected into the abdominal cavity has an important stimulating action on the cardiovascular and respiratory system; it prevents the formation of adhesions, induces hyperemia and promotes healing, and in case of intraabdominal septic effusions, arrests absorption of septic fluids. Its curative action is enhanced if it is transformed *in situ* into ozone by Roentgen-ray exposures. The oxygen is introduced in a continuous flow through a buttonhole in the anterior abdominal wall and it flows out through various drains, the cavity thus being continually flushed by the gas. It forces out along with it pus and serous effusion, aiding materially in the draining and cleansing of the cavity. Weiss and Sencert give the details of 5 cases in which oxygen irrigation was applied, and will continue their report in the next number of the *Revue*.

83. **Idiopathic Hematuria.**—Robinson and Jacoulet discuss hematuria of angioneurotic, toxic, portal and varicose origin and hematuria from efforts, showing that medical treatment may give good results in all these forms of so-called idiopathic hematuria. It is beyond question, they state, that hematuria may occur without any lesions in the kidney, and that medical treatment will generally prove successful. If operative interference becomes necessary, nephrotomy is the best technic for the purpose, followed by suturing. Nephrotomy seems to have a double action, relieving congestion at once and later reducing the arterial afflux by obliteration of some of the vessels. The functioning of the kidney does not seem to be affected by incision and prompt suturing of the kidney, owing to the compensating hypertrophy of the intact parts of the organ. The various experiences that have been published are reviewed in detail. The view formerly accepted that some lesion in the kidney always preceded the hematuria has been disproved, the authors assert, by the later experiences and researches.

84. **Ischemic Paralysis and Contracture of Volkmann.**—Binet's monograph is based on 141 cases including one from his own experience, and discusses the cause and treatment. He states that the physician cannot be regarded as responsible for this syndrome except in case of great negligence. In treatment the best technic is by a plastic operation on the tendon with resection of the radius and ulna, which seems to be the only means for radical treatment of this ischemic retraction.

85. **Paralysis from Dislocation of the Shoulder.**—Delbet and Cauchoix insist on the importance of operative treatment as early as possible before the sclerous perineuritis completely destroys the conducting power of the nerves. They have found thirty-six cases on record which they review in detail with the technic for operative treatment.

109 Experimental Research on Surgery of the Bronchus. M. Tiegel.

99. **Operative Treatment of Jacksonian Epilepsy.**—Finsterer reports that he introduced a piece of hernial sac under the dura to prevent the latter's growing to the pia and brain below. This was done at a second operation, the first having been done to remove a splinter of bone, and the second to correct the adhesion of the dura to the brain. Hacker has been using for some time pieces of hernial sac, obtained at a herniotomy on another patient, as an effectual means for preventing the growing together of tissues in operations on tendons and nerves, and experiments on animals have confirmed the advantages of this material for use under the dura. The results have been followed for a year to date in some of the experiments. In conclusion, Finsterer reports a second case in which the subdural implantation of a piece of hernial sac has also put an end to the disturbances to date; it was done at the fourth operation in this case, the implantation of a celluloid plate not having arrested the convulsions for more than a year.

102. **Ultimate Outcome of Operations for Jacksonian Epilepsy.**—Cluss reports a case in which the patient was operated on over 18 years ago for Jacksonian epilepsy and has had no further signs of the trouble since the operation. The patient at the time of the trauma was 24 years old; the first operation revealed a subdural cyst in the cortex which was excised. A few mild seizures were observed during the first six months after the operation but none since then. In connection with this case he reviews 21 others in the literature in which operative treatment has been followed by a cure for more than 3 years. Recurrence has been known even after an interval of 3 or 5 years of apparent health. Patients under the age of 30 are more liable to complete recovery after operation. The duration of the latency or active phase of the epilepsy does not seem to have a decisive influence on the results of surgical treatment. The prospects of benefit are better when there are gross local changes than in the absence of such. Temporary resection of the skull is advisable, he believes, to obtain insight into conditions. The dura should be incised, but it is not necessary to make a dura valve, and neither is it indispensable that the center involved should be resected. Paralysis from resection of brain substance generally disappears entirely after a time.

107. **Tuberculous Stenosis of the Pylorus.**—Tappeiner reports a case in which a boy of 12 had suffered for about 9 months from pains in the stomach and vomiting, rare at first but gradually becoming more frequent until they occurred after every meal and the child lost 17 pounds in weight. On the diagnosis of pyloric stenosis gastroenterostomy was done, and great improvement followed. The stenosis proved to be, as suspected, of a tuberculous nature but the child's condition did not permit resection. In 26 similar cases of tuberculous stenosis in the literature, resection was done in 8 cases, and in the others gastroenterostomy, excision of the ulcer, pyloroplasty or merely an exploratory laparotomy. Nearly all the patients succumbed within a year to the progress of the tuberculosis in other organs. In 4 cases the patients were under 20, in 7 over 40.

112. **Preventive Serotherapy for Tetanus.**—Bär reports two cases in which preventive injection of 10 c.c. of antitetanic serum did not prevent the development of the disease, although in one the symptoms were restricted to the arm, the local tetanus running its course to recovery in a week. In the other there were no symptoms for four weeks when fulminating general tetanus developed.

118 *Dilatation of Prostatic Urethra in Treatment of Hypertrophy of the Prostate. (Zur Behandlung der Prostatahypertrophie durch Prostatadehnung.) F. Kraemer.

113. **Nature and Treatment of Hysteria.**—Romberg explains hysteria as a congenital morbid disturbance in the course of

associations; in hysterical anesthesia the periphery feels, the spinal cord conducts and the central convolution receives, but the complicated phenomena on the other side of the cortex are lacking. No conscious impression results. If it is possible to restore the association here normal conditions return, and some slight impetus may restore the consciousness which awakes like the sudden remembrance of a word that has momentarily escaped the memory. In children and in persons whose mental development is not much beyond that of childhood, this restoration occurs particularly easily because the physiologic development favors the reception of new associations. Thus the child hangs on the words of the story-teller while it is difficult to fasten the interest of adults. In treatment it is important to accept the disturbances as real. It is wrong to exhort patients to exert their will; the aim should be to divert attention from the disturbances. He remarks that many cases of hysteria in children are really only the hysteria of the mothers. It is important, he adds, to seek to train the abnormally functioning associations, especially by light systematically increasing work. This diverts the mind, which pleasure, theaters, etc., fail to accomplish. The measures which cure by a sudden impression are more liable to be effectual with children and persons with uncultivated minds. The after-treatment is extremely important following a cure of this kind, not allowing from any one expressions of surprise or suggestion that the trouble had been due to the lack of will power. The recovered functioning should be promoted by systematic exercise. The main point is to have the physician win the confidence of the patient and avoid everything tending to mysticism, especially hypnosis.

114. **Differentiation of Neurasthenic Pains.**—Kollarits calls attention to the fact that neurasthenic pains are generally improved by movement, contrary to the pain in true rheumatism and arthritis. This applies also but less constantly to neurasthenic palpitations and pseudoangina pectoris. The physician should ask whether the pain is increased by movements or walking or becomes less, with care to refrain from suggesting the answer. With the attack of neurasthenic pain, the patient generally jumps up and walks to and fro, during which the pain subsides. The attack of pain is often accompanied by general restlessness, palpitations and sweating. The neurasthenic pain in a joint is not very violent but is more a sensation of pressure or smarting. Neurasthenics are generally extremely sensitive to heat and to constriction from tight collars. Nervous pains are not benefited by hot water treatment; exercise in the open air is the main reliance. Kollarits adds that if digitalis is given at all, it must be given with great care as it is liable to do harm if the patient knows he is taking digitalis, this confirming him in the idea of organic heart disease.

115. **Traumatic Neurosis After Concussion of the Brain.**—Friedmann states that no one needs to be spared so much as a patient during the first two years after a concussion neurosis. Increasing experience with industrial accidents has taught that the course is toward gradual improvement to complete recovery, even with concussion of the brain. After from 4 to 7 years from 60 to 70 per cent. of the patients may be regarded as essentially cured. The worst factor in the matter of traumatic neuroses, he declares, is not the patient's weak will nor his desire for sick pay, but it is the attitude of the employers who dislike to employ these semi-invalids. Partial earning capacity is therefore about equivalent with total incapacity and the injured workingman has every reason to strive to obtain the highest possible indemnity, especially if he is near the age of 40.

116. **Comparative Research on Wassermann and Globulin Reactions and Lymphocytosis in Differentiation of Nervous Disease.**—Wolff tabulates the findings with these three tests applied to the spinal fluid, remarking that the globulin reaction is the most instructive as it is invariably negative when there is no existing parasyphilitic or metasyphilitic nervous affection, even with a history of old syphilis. (The globulin reaction or "phase I" was first described by Nonne and his work on the subject was published in The Journal July 24, 1909, page 289.) The Wassermann and globulin reactions in the spinal fluid were constantly negative in 6 cases of neurasthenia and 6 of epilepsy, while the globulin reaction was always positive in 40 cases of tabes, 30 of paralytic dementia, and 7 out of 8 cases of cerebrospinal syphilis.

118. **Treatment of Hypertrophy of the Prostate by Dilatation of the Prostatic Urethra.**—Kraemer followed Bayer's advice as a last resort in a recent severe case of enlarged prostate, the patient having refused to submit to an operation, and began systematic dilatation of the constricted upper end of the urethra. The patient was a man of 66 who after a five-day attack of ischuria was unable to void normally a drop of urine for more than five weeks. Then dilatation was commenced, using first a Béniqué sound, caliber 23, 24 and 25 French. In the course of 11 days and 8 sittings the caliber was increased gradually and the dilatation was finally completed with a rapid dilator, the lumen thus being opened to a caliber of 44, equivalent to a lumen of 1.6 cm. When any blood was noticed in the urine a retention catheter was introduced and left for a day or two. By the end of the 11 days the patient was urinating spontaneously without trouble, and when last heard from, a month after the dilatation, he was spontaneously voiding an average of 2 liters of urine daily. Bayer uses a special dilator with which he is able to dilate the lumen to 2 cm. without injury of the urethra as he determined by tests on the cadaver. In his 11 cases, 4 of the patients were permanently cured, he states, and 3 materially improved, but no benefit was derived in 3 other cases with extreme hypertrophy and cystitis. Kraemer did not attempt the dilatation until after he had cured the complicating cystitis by appropriate measures in his case.

Medizinische Klinik, Berlin

April 24, VI, No. 17, pp. 653-690 and Supplement

119 Operative Treatment of Extreme Myopia. (Operation der Kurzsichtigkeit höchsten Grades.) W. Goldzieher.
120 *Thickness of the Adipose Tissue in Abdominal Wall as Index of Condition of Nourishment in Adults. (Die Fettpolsterdicke als index der Ernährungszustandes bei Erwachsenen.) G. Oeder.
121 Transplantation of Tissues. (Zur Gewebstransplantation.) C. Ritter.

124 Therapeutic [illegible] Thermal Waters. Chabrol.
125 *Pericarditis [illegible] Klinik der Pericarditis exsudativa.) R. Bernert.

120. **Thickness of the Abdominal Wall as Index of State of Nourishment.**—Oeder has been seeking for years for some means to express the general state of the nourishment of patients and has tabulated the findings in regard to height, weight, size, chest measure, etc., but no formula that he was able to work out from them seemed to express the actual condition of the nourishment. On the other hand, the thickness of the layer of adipose tissue in the abdominal wall seems to be directly proportionate to the general state of the nourishment. In 1,920 separate examinations he found 936 persons of the lean type, 607 of the normal and 377 of the fat type. He estimates the thickness of the fat by taking up a fold to the right of the umbilicus and measuring it with calipers. With the lean type the fold measures from 0.75 to 3.5 cm., averaging 1.1 cm. or nearly half an inch; with the normal type about 2.75 cm., or 1⅛ inches, and with the fat type, 4.41 cm., or 1¾ inches. All adults therefore with this index larger than 2 inches should be regarded as abnormal, as also those with an index of less than ⅜ inch. The difference for sex, age and height is so small that it can be disregarded. This index may throw light on individual indications, whether more nourishment is needed or more exercise, and when normal conditions have been attained under dietetic or other treatment.

122. **Occult Hemorrhage in Gastrointestinal Tract.**—Kuttner reviews the information to be derived from discovery of occult blood in the stool or stomach content but he warns that many causes may be responsible for it. Occasionally the occult bleeding may give the clue to the correct diagnosis, but, as a rule, its discovery does not throw light on the diagnosis but tends to make it still more laborious.

125. **Pericarditis with Effusion.**—Bernert reports 4 cases of pericarditis with effusion in which there were a number of

atypical features. The patients were young men between 21 and 24 and the extensive effusion occurred again and again, but seemed to be entirely absorbed during the intervals. The intermittent-remittent effusion developed and was reabsorbed with remarkable rapidity. In one case there was nothing left of the large effusion by the end of the week; then it rapidly returned but subsided anew within 2 days and not a trace was left by the end of another 3 days. Another striking feature of the cases was the sac-like protrusion of the left lower side of the pericardium. In some of the cases the pulse was smaller in the left carotid and radial arteries than in the corresponding vessels on the right side, but this sign of compression from the large pericardial effusion disappeared as the effusion retrogressed. The same cause may induce transient dilatation of the pupil on one side from irritation of the sympathetic. The involvement of the phrenic nerve may entail paresis of half of the diaphragm and hiccough and involvement of the vagus, vomiting and violent coughing. He discusses in detail the percussion findings with this atypical intermittent form. There was a history of acute articular rheumatism in only one of the four cases reported; the others were evidently of tuberculous origin. Enlarged glands at the hilus of the lung were manifest in each. In all the cases the affection progressed to adhesive pericarditis.

129 *Rupture of the Symphysis During Delivery. L. A. Kriwski.
130 *Indications for and Advantages of Cold Irrigation of the Vagina. (Ueber kalte Scheidenirrigationen.) T. Alexandrow.
131 Intraperitoneal Shortening of the Round Ligaments. (Ueber intraperitonealer Verkürzung der Ligamenta rotunda.) M. Hirsch.

128. **Treatment of Rupture of the Uterus.**—Issel reports 9 cases of rupture of the uterus during delivery. The 2 fatalities were from peritonitis resulting from the reduction of the intestines prolapsed into the vagina, five hours before the operation, in one case, and from hemorrhage on the operating table in the other case. Immediate ligation of the hypogastric and ovarian veins on both sides is an important factor in treatment; it spares the patient further loss of blood and the operation proceeds in a bloodless field. He advocates prompt abdominal hysterectomy, as fatal rupture is peculiarly liable at a later pregnancy when the first rupture was given merely conservative treatment. The communication issues from Krönig's obstetric service at Freiburg. The general practitioner is advised to send the patient to a hospital as soon as the rupture is discovered, refraining from any attempt to complete the delivery. The experience of Schütte, Petren and others that these ruptured women are able to stand transportation even from a considerable distance was confirmed in Issel's cases, one patient being brought from a neighboring town to the clinic. The patient either succumbs at once to the hemorrhage—which is rare—or small repeated hemorrhage occurs, allowing time for the woman to be taken to a hospital. If conditions are favorable, the abdominal hysterectomy can be done in the home. If institutional care is not attainable, the delivery can be cautiously completed, followed by tamponing, or if the hemorrhage is not severe, by merely draining the wound cavity. With one exception, a primipara of 29, his patients had all borne from 5 to 8 children. In this case the posterior vault of the vagina was accidentally perforated about 3 hours after spontaneous childbirth, during an attempt to separate the placenta by hand. The abdomen was opened and the vaginal wall found torn from the uterine cervix; the tear was readily sutured and the abdomen closed without further interference. The patient was discharged cured after passing through a severe puerperal fever. Hysterectomy was done in all but one of the other cases, with or without leaving the adnexa intact on one or both sides.

129. **Rupture of the Symphysis During Delivery.**—Kriwski's patient was a woman of 33 who had already borne 6 children, the deliveries being normal and unusually rapid. The seventh pregnancy had been preceded by typhoid; after the onset of labor there were two attacks of convulsions and labor was prolonged for over 24 hours. Then forceps were applied and a very large child delivered. A cracking sound was heard during the traction with the forceps, and after extraction of the child blood issuing from the urethra directed attention to the rupture of the symphysis; two fingers could be inserted in the gap. The hemorrhage soon ceased spontaneously and the patient recovered without further mishap except for persistence of tenderness in the sacral region and incontinence of urine. She did not complain of pain or tenderness in the symphysis at any time. The tendency to incontinence seems to be growing less; it is probably the result of some tear in the urethra near the sphincter.

130. **Application of Cold in the Vagina.**—Alexandrow uses a coil of tubing wound so as to fit over the cervix and against the deeper vaginal walls, and sends ice water through the tubing. His experience with this cold irrigation, he says, has been gratifying in the suitable cases. He describes some of his clinical experience and his experimental research in this line, reiterating that both cold and hot applications should be regarded as important therapeutic measures in treatment of the female sexual organs. Cold irrigation is indicated to enhance the action of unstriped muscle, either in the vessel walls or in the supporting ligaments. Hot irrigations are useful to increase the absorbing power of the vascular apparatus, as the arterial hyperemia induced favors absorption of effusions in the pelvic connective tissue or peritoneum. The cold irrigations are useful, he states, with subinvolution of the puerperal uterus from weakness in the uterine musculature and vessel walls. The temperature in the region is reduced much more than by application of an ice bag outside. In one of the cases reported the gravid uterus had become incarcerated and the cold irrigation was applied twice for half an hour to prepare the uterus for the supposed inevitable operation, but this proved unnecessary, the cold having evidently caused such contraction of the uterine musculature that the organ, thus reduced in size, had spontaneously righted itself.

135. **The Meiostagmin Reaction in Typhoid, Etc.**—In this communication Izar gives the details of the application of the test for changes in the drop-forming property of the serum in various diseases, this being the material on which the preliminary report was based, mentioned in The Journal, April 2, 1910, page 1177.

136. ***Nature and Treatment of Carcinoma.***—Theilhaber and Greischer discuss the statistics gathered by F. Theilhaber which showed that carcinoma of the uterus is comparatively infrequent among the rich and among Jewish women, while mammary carcinoma is far more frequent among the unmarried, the rich and Jews. He ascribed this fact to the lesser number of pregnancies, tight lacing and racial peculiarities. Greischer has also found gastric cancer more frequent among the poor and especially frequent among cooks, while rectal cancer is more liable to be encountered in the rich, and most frequently of all in men holding high official positions. As a whole, they state, there are more cases of cancer among the rich, and the disease develops at a later age. Cancer is more frequent among the Jews, they believe, all organs inclusive. The mortality from cancer has doubled at Munich during the last

forty years. Theilhaber ascribes great importance to cicatricial tissue as a factor in the development and especially in the recurrence of cancer. Trauma and cicatrix disturb the metabolism in the mesodermal tissue and this permits encroaching proliferation of ectodermal elements. Normally the mesoderm holds them in check and he suggests that possibly an extract of mesodermal tissue might prove effectual in checking the growth of incipient cancer or preventing recurrence. He adds that possibly in the attempt to remove all morbid tissue the operative trauma has been made unnecessarily extensive. It is certainly suggestive, he remarks, that Schröder had 19 patients radically cured after an interval of 4 years out of 96 who had survived resection of the cervix 30 years ago on account of cancer. This incomplete operation evidently left morbid elements but the organism was able to cope with them. As a logical consequence of his view he suggests the advisability of means to prevent development of cicatricial tissue and to promote normal conditions in the region by artificially inducing hyperemia with application of heat, electricity, stasis and suction devices, wet cupping and, with uterine carcinoma, hot vaginal douches and ingestion of ovarian substance.

147. Operation for Total Prolapse of the Uterus.—Jolly describes with illustrations his technic for operative treatment of total prolapse of the uterus which he has applied in thirty-three cases in Olshausen's gynecologic service at Berlin. The method, he says, is similar to that recently published by Polk, but he operates exclusively by the vaginal route. Two of the patients succumbed to pulmonary embolism, another to diabetic complications. The high mortality from embolism may be due, he thinks, to the injury of the veins in the floor of the pelvis during the posterior colporrhaphy. Pulmonary embolism occurred in 6 out of 500 other operations requiring this colporrhaphy during the last few years in the service while in a preceding series of 634 cases there were only 2 deaths from this cause. Not until the last few years has it been the practice to take the deep suture in the musculature of the floor of the pelvis, and it is a question, he remarks, whether the advantages of this technic outweigh the danger of pulmonary embolism. Simple removal of the prolapsed uterus alone does not protect against recurrence, but with the technic described it seems to be possible to ensure a solid and well-shaped vagina. The ultimate results have been excellent in all the cases in which it has been applied.

148. Adenomyoma of the Uterus.—Yamasaki concludes from the case reported and what he has learned from the literature that total hysterectomy is the only means of certain cure in adenomyoma of the uterus.

151. Cesarean Section.—Flesch protests that the question as to the best technic for Cesarean section is merely that as to the possibility of simultaneously sterilizing the woman so as to prevent further conception. When conditions are so serious as to demand Cesarean section and there is no prospect for future normal deliveries, he combines tubal sterilization with the operation. The question of a supplementary sterilizing operation should be considered in cases of manifest deformity, severe rachitis, osteomalacia and a tendency to placenta prævia, but not for eclampsia, as this affects predominantly primiparæ although serious chronic impairment of the kidneys may afford an argument in its favor in some cases.

156 *Plastic Operation after Resection of Shaft of Long Bone. (Ueber Knochenplastik nach Resektionen an langen Röhrenknochen.) W. Bittner.

156. Plastic Operation After Resection of Shaft of Long Bone.—Bittner resected the lower half of the tibia down to the epiphysis on account of sarcoma. The gap thus left was filled with a corresponding piece cut out of the remaining upper half of the same bone. With the wire saw and chisel the tibia was cut in half up into its tuberosity, and the portion thus mobilized was turned over downward, bringing the upper part down to the epiphysis where it was sutured. A wire also held the lapping ends of the bones together in the center. The leg was put in a plaster cast for some time, with which the child, a girl of 13, was allowed to be up and about after the sixth week. The result has been satisfactory; the leg is scarcely 1.5 cm. shorter than its mate and can be normally used. The illustration accompanying the article is stated in a later issue to be incorrect, and a corrected view of the technic is given on page 644.

161 Improved Forceps for Seizing the Uterus. (Uterushaltezange mit abnehmbaren Griffen.) M. Hirsch.

159. Digital Compression of the Aorta for Postpartum Hemorrhage.—Engelhorn comments on the hard, retracted condition of the uterus when there has been much loss of blood, Nature evidently striving thus to arrest the hemorrhage. The frequency of this explains the great rarity of directly fatal postpartum hemorrhage. Momburg's belt constriction arrests postpartum hemorrhage by the same means, the shutting off of the blood supply starting vigorous retraction in the uterus. He is convinced that the same effect can be realized by systematic compression of the aorta with the fingers, pressing it back against the spine until the femoral pulse ceases to be perceptible. In two normal cases in which this compression was applied for 150 pulse beats, the uterus contracted vigorously and the placenta was early expelled. This also occurred in a case in which extreme atony had been the rule in three previous pregnancies with threatening hemorrhage each time. Immediately after the birth of the child the aorta was compressed in this way for 150 beats and the uterus contracted normally. At any sign of relaxation the compression was applied anew for a minute or so. Each time the uterus responded with a contraction and there was no abnormal hemorrhage. Similarly good results were obtained in another case in which part of the placenta had to be removed by hand. Engelhorn adds that to Momburg belongs the credit of calling attention anew to the advantages of this simple method of controlling uterine hemorrhage and the means of control by the femoral pulse becoming imperceptible.

168 Occult Blood in Stools with Trichocephalus. (A proposito della "reazione di Weber e tricocefalo." M. V. Carletti.

167. **Gynecologic Expert Testimony in Murder Case.**—Bossi gives the bases for his testimony in a recent murder case at Venice in which for the first time a gynecologist was called on for his specialist opinion. The accused was a Russian woman with a history of insanity in the family, married at 16, the menses always irregular and painful. She had been left with chronic inflammation in the adnexa after her second pregnancy ten years before; the uterus was three times the normal size and bound down in retroflexion, interfering with the bladder and intestine functioning, and thus entailing more or less stagnation of the intestinal content and of the urine and of the secretions in the abnormally flexed uterus. He testified that the resulting persisting autointoxication must have had an injurious effect on the material and psychic functioning of the nervous system.

173 The Mechanism of Gallop Rhythm. (Sul meccanismo del ritmo di galoppo.) C. Pezzi.

169. **Shortened Technic for Exclusion of the Pylorus.**—Parlavecchio comments on the advantages of exclusion of the pylorus under certain conditions but states that the operation is so long and tedious that many shrink from it on this account when otherwise it might be indicated. He now proposes a simpler method than the von Eiselsberg technic hitherto generally used. On dogs it required only from 2 to 4 minutes longer than a simple gastroenterostomy. Instead of cutting off the pylorus from the rest of the stomach he merely throws a ligature around it at the point where the incision would be made by the usual technic, thus shutting off the region of the pylorus as completely as if it had been resected. He uses a strong, non-elastic ligature and proliferation of cicatricial tissue soon completely shuts off the part beyond.

171. **Treatment of Infectious Nephritis.**—Arcangeli analyzes his experiences with nephritis at the Rome policlinic, his conclusions being that the specific drug indicated should be used without paying too much attention to the influence it may have on kidney functioning; especially in syphilitics it is hard to know whether the nephritis is of syphilitic nature or not. With negative Wassermann findings, he advises against mercurial treatment. Diphtheria antitoxin is useful, he states, in the nephritis that accompanies diphtheria. In streptococcus or staphylococcus nephritis he advises vaccines used according to Wright's technic; this may also prove useful in nephritis from the diplococcus, etc. In acute nephritis with fever his experience warns against the use of drugs to reduce the fever and also of heat to induce sweating, but the fever should not be left untreated, and for this he advises cold hydrotherapy, graduated to the intensity of the fever.

Address

SOME PUBLIC HEALTH PROBLEMS*

G. MILTON LINTHICUM, A.B., A.M., M.D.
Professor of Physiology and Proctology, Baltimore Medical College
BALTIMORE

In view of the present active crusade for increased efficiency in all lines, I feel it pardonable to bring to your attention at this time some matters pertaining to health. Not that I can add to your knowledge of the subject, but only by frequent iteration is it possible to impress on the public mind the importance of these questions. General information is only of slight value, beyond adding to our self-complacency, and deluding ourselves as to what we really know. It is only when we analyze our information that we learn how vague our ideas are.

Hence my plea for indulging in a somewhat frayed-out topic is, that in reviewing the literature of our state and national health conditions, one is struck with two great truths: first, how enormous has been the success in dealing with many dread diseases, such as smallpox, plague, typhoid fever, cholera and yellow fever, all of which has been made possible by scientific investigation and data obtained largely through the labors and sacrifices of our profession; second, with the great fields yet to be cleared which are growing up daily from the seed sown by the previous crop of tares, and that these huge problems of health, state and national, are to be solved, I feel, largely by the medical profession, the biologist and the biologic engineer; and the latter must in course of his preparation pass through a medical training to understand his work.

To these achievements of the past I shall refer briefly in order that the possibilities of the future may be forecasted.

SMALLPOX

The marvelous results of vaccination are incomprehensible to present-day physicians. I have seen but three cases of smallpox in sixteen years of practice, and the patients were in quarantine. Before Jenner's discovery, slightly more than a century ago, the toll demanded from the human family was one-tenth of the deaths from all causes. During the eighteenth century it is computed that at least 50,000,000 persons died of this one disease. Prior to compulsory vaccination in Prussia in 1874, it having been used intermittently up to that time, the death-rate was 24.4 per hundred thousand; during the next decade it fell to 1.5 per hundred thousand.

As early as 1826 Denmark had compulsory vaccination, and has enforced it so vigorously that not a case has occurred in ten years. Havana for eight years prior to its occupancy by the Americans reported 3,123 deaths from smallpox. In 1899, a year after our entry, there were four deaths and only three in the next seven years, a practical elimination of a scourge which had always existed prior to this time. This illustrates two factors—the entire prevention of a disease by a scientific immunizing agent, and the need of such laws as will protect the whole people, though this to some appears as a sacrifice of individual rights.

This plea for personal liberty, arising in the Old World, has invaded our land, and groups of obsessed and hysterical individuals have formed a society for attacking vaccination. These people band themselves together under the head of antivaccination societies, and by specious arguments endeavor to influence the uninformed as to the possibilities of disease being inoculated into them by vaccination. It remains for us then, to enlighten the people at large relative to the facts concerning vaccination, that their misleading arguments may be forestalled.

The freedom from smallpox which has been brought about only through vaccination is being used as an argument for legislation against the very agent which has made the controversy possible.

YELLOW FEVER

Yellow fever in 1793, during a period of six and a half weeks killed one-tenth of the entire population of Philadelphia. Since that date approximately 500,000 cases have occurred in the United States, one-fifth of which terminated fatally. In 1900 experimenting by Lazear and Carroll Reed on themselves—having a certain species of mosquito (*Stegomyia*) inoculate them—confirmed the work of previous and coincident workers as to the true carrying agent of this malady, but sacrificed their noble lives that the world might be informed and many lives saved. So to-day as a result of this sacrifice, our country is practically free from this disease.

Havana has paralleled the elimination of its smallpox by reducing its cases of yellow fever from a death-rate of 639 to 100,000 people in 1896 to 4.3 to 100,000 two years later. These results have been due to protection from the mosquito and the general cleaning up and enforcing of the sanitary measures by General Wood and Colonel Gorgas.

Panama, under Colonel Gorgas, has been changed by sanitary means from a region fatal to life by virtue of disease into one as free of disease as the average country. Indeed, it may truly be said that sanitary science is building the Panama Canal, that its completion will be the most enduring monument to preventive medicine; and as the two great oceans commingle their waters, and as the world gazes on the majestic ships as they pass to and fro, it will perhaps be realized that the power of man is supreme over inanimate matter. This will give to all mankind the true faith and belief that the knowledge of sanitary engineering will increase, so that as the Panama Canal represents the completion of an undertaking of vast proportions, so will the causes of diseases be eventually circumvented.

---

* President's Address to the Members of the Medical and Chirurgical Faculty of the State of Maryland Annual Meeting, April 26, 1910.

CHOLERA, SCURVY, TYPHUS AND DIPHTHERIA

Cholera, formerly the scourge of the Atlantic seaboard, is now, since the discovery of its cause, practically a thing of the past.

Scurvy, which in the eighteenth century decimated the armies and navies of Europe, has been eliminated by the discovery of its cause, which was proved to be faulty nutritive and metabolic processes dependent on the deficiency of vegetable juices.

Typhus fever, popularly known as ship fever, jail fever, a scourge which ravaged the civilized world for centuries, is so rare now that I question if there is a practitioner in this audience who has seen a case in his whole experience. A disease of filth, overcrowding and lack of sanitation, its elimination has required only cleanliness, light and air.

Diphtheria, the very name of which brought terror to the heart of the mother and blanched the cheek of the father, has been robbed of its fangs, the mortality having been reduced from more than 40 per cent. to as low as 4 in cases recognized early.

LABORATORY INVESTIGATION

Here improved sanitation has not availed in its arrest, but the laboratory has brought about a curative serum, to which method alone we must give full credit for relief from this dread disease. I can do no better than to quote the closing remarks of a paper read by Dr. William H. Welch in 1895, for it emphasizes two factors so well; the value of laboratory methods, and animal experimentation:

> The discovery of the healing serum is entirely the result of laboratory work. It is the outcome of the studies of immunity. In no sense was the discovery an accidental one. Every step leading to it can be traced, and every step was taken with a definite purpose and to solve a definite problem. These studies and the resulting discoveries mark an epoch in the history of medicine. It should be forcibly brought home to those whose *philozoic sentiments outweigh sentiments of true philanthropy*, that these discoveries which have led to the saving of untold thousands of human lives, have been gained by the sacrifice of the lives of thousands of animals, and by no possibility could have been without experimentation on animals.

Indeed, with the vast amount of material facts already collected, and with the results thus far obtained, the retrospect is assuring for the future.

The health problems present two phases which should be considered, as they are of equal importance, from both an economic and a humanitarian view-point. The improvement in our vital resources will result in increasing the span of life as well as decreasing disease during life, thereby prolonging the period of productiveness, and at the same time adding proportionately to the well days during life, in the same ratio as disease is lessened. Thus, as it has been said, we add to the breadth as well as to the length of life.

SANITARY SCIENCE AND PREVENTIVE MEDICINE

If one compares countries where sanitary science and preventive medicine have sway with those not so regulated, the results are astounding. In India the average lifetime is less than twenty-five years. In this country it is forty-four years, taking Massachusetts as a criterion, this being the only state with a long accurate vital statistical record. The increase from century to century shows the marked effect of sanitation. India remains stationary. In Europe the average lifetime has doubled in three and a half centuries. The increase was approximately four years per century during the seventeenth and eighteenth centuries, while the first half of the nineteenth century showed an increase of about nine years, and the latter at least seventeen years.

Germany, the country of advanced sanitation and prevention, shows an increase of about twenty-seven years in a century. In this country, Massachusetts as a basis, the increase is only about half that of Germany.

When we compare the average lifetime in India with that in Sweden, and find it only half; and when we further compare all the intermediate statistics of various countries, we find that *the length of life is directly proportional to development of sanitation.* The conclusion is obvious, that the length of the human life can be prolonged or shortened by a change of those conditions on which it directly depends.

It is estimated that in the United States at least 3,000,000 persons are seriously ill all the time. Of this number one-sixth or 500,000 are sick of tuberculosis, of whom 150,000 die annually. *It is believed that at least three-quarters of this number could be saved by preventive measures.* The death-rate from tuberculosis in England is now only one-third of what it was seventy years ago.

This gradual decrease of deaths from tuberculosis, giving England a lower rate for this cause than any other country, is explained by *Dr. R. W. Phillips of Edinburgh.* He states that:

> The legislation of the past three-quarters of a century with regard to the dwellings of the poor, lodging-houses, work-shops and factories, and other public health enactments, have paved the way for the more direct attack. Through the influence of these measures mortality from tuberculous diseases has as *steadily lessened as that from other infectious conditions.* There can be no doubt that the housing question, using that phrase to include all considerations relating to dwellings, lodging-houses, schools, factories, etc., must occupy a chief place in the preventive program against tuberculosis.

This phase of the subject is one which needs more attention, particularly in this and other southern states where tuberculosis is so prevalent and so fatal in the negro race. When we realize that a large majority of people, estimated at 90 per cent., are all, at one time or another, affected with tuberculosis, and that but 10 per cent. die, enormous as this makes the grand total, we are justified in saying that in few diseases not self-limited is there a greater tendency to recovery than in tuberculosis. This one problem must be solved by a full realization on the part of those in legislative power of the possibility of prevention, by the enactment of suitable regulations, and appropriations of sufficient funds to properly enforce them. I feel that Maryland has been no laggard in this fight, and that its work will show remarkable results in another decade.

PROTECTING WATER-SUPPLY

Typhoid fever exists throughout the United States to an enormous extent, the most of which has been directly attributed to the water-supply. Aside from the great financial loss and distress of mind in the care of cases of typhoid recovering, it causes 2 per cent. of all deaths, and it is generally conceded that Hazen's theory is correct, that every life saved from typhoid by better water-supplies, means two or three lives saved from other causes. The improvement of the water-supply of various cities has enormously reduced the occurrence of cases.

But there is a feature of the disease which we, as physicians should not lose sight of. It is to-day largely a rural disease, because of the proximity of wells to habitations; and the well in which hung the old oaken bucket has been the cause of many of the sad scenes of our childhood. The purification of these sources of water-supply cannot be attained by measures in rural districts corresponding to those employed in large cities, such as expensive filtration plants.

This condition can and should be met by the physician, first of all he should recognize the disease; and this in most instances may be more readily done by the improved methods of diagnosis. Secondly, he should realize that the disinfection of feces and urine will destroy the possible contamination of the drinking-water. Thirdly, he should make sure of protection from the "typhoid fly" carrying the germ from patient to food and drink. Finally, the usual sick-room precautions should be observed. Thus can we as physicians be the greatest factors in this fight. When we destroy the source of contamination, all water-supplies will remain pure.

I do not deprecate the necessity for modern sanitary water-supplies for large centers; they are of vast importance; but suitable precautions taken will reduce this disease to a minimum, even under the present arrangement.

We know that typhoid is a water-borne disease. The pollution of interstate waterways is the cause of a tremendous loss of life, and it is a problem which has led to the question of the power of the government to eliminate this evil without interference with state rights. Without exhaustively discussing this legal constitutional question, I may only quote without giving details, an opinion given by ex-Congressman George Shiras, son of Justice Shiras, to Surgeon General Wyman:

> The right of a government to regulate and control the extent and character of water pollution is a primary one and may, in the United States, be divided into two general classes: First, local waters, or those lying wholly within the confines of a single state. Second, interstate waters, or those traversing or lying within the territory of two or more states. In the first division, the sanitary jurisdiction over local waters is limited to the state courts, and all remedial or corrective legislation is vested solely in the law making body of the state. In the second division, however, the jurisdiction over the interstate waters may be a concurrent one of the state and federal governments, or at times, when the conflicting interests of the state in such common waters requires the intervention of a final arbitrator, the federal government becomes supreme in its determination of what constitutes an unreasonable and unnecessary pollution of waters common to two or more states. Thus it simply remains for the people to realize this danger and demand the proper protection.

The pollution of water-supplies from sewage is becoming daily a more and more serious problem. With the extension of rapid and convenient transportation, the suburban sections are becoming crowded; cities as dwelling-places are no longer appreciated; the tendency is to go to the country. In consequence of this there are many communities located along streams furnishing drinking-water to other communities, where no adequate provision is made for the disposal of the sewage, resulting in a constant saturation of the soil and pollution of streams. There must be some way of solving this problem. Health ordinances must be enacted for the suburbs as stringent as those for the city, if a serious condition of affairs is to be prevented. The pollution of streams within the state must be prevented by state authorities, and it is regrettable that it often seems difficult to enforce such measures. The people have the power in their hands. Public sentiment must be aroused.

PNEUMONIA

The number of deaths from pneumonia is somewhat greater than that from tuberculosis. This disease causes 11 per cent. of all deaths in the United States, as shown from the mortality statistics of the registration area by the last census. Our knowledge of it is confined to its cause, its communicability and the wide distribution of its germs. The predisposing causes have been observed to be those things which lower the vital resistance, such as alcoholism, acute or chronic, exhaustion, exposure, and insufficient clothing or food. The means of its prevention by health measures, other than maintaining a high condition of vitality, are not known. It is therefore, a formidable problem for the laboratory man to solve as he has solved that of diphtheria.

MALARIA

Malaria is preventable and is decreasing rapidly throughout the country. It can be absolutely eliminated in one of three ways: first, by eliminating the parasite from the blood by quinin or other therapeutic measures; second, by preventing the mosquito from biting a malarial patient and becoming inoculated, or by preventing the mosquito which has become inoculated from biting the non-inoculated person; third, by destroying all mosquitos by sanitary measures. I believe the first method, by the unstinted use of quinin, has thus far been the chief factor in the reduction of malaria, and I believe the cheapening of quinin to make it available was one of the greatest economic blessings the American people has ever had. Malaria is not a disease with a high mortality, but wherever and whenever it prevailed, the country or state of the country was markedly backward in its development. It is said the decline of the Roman Empire dated from the time the people discontinued the custom of anointing their bodies with olive-oil, thereby permitting the mosquito to bite and inoculate them with malaria, for a mosquito declines to bite through a film of oil.

While I am sure that everyone feels that malaria was only one of the many factors in the decadence of those wonderful seats of civilization, and that social degeneracy was really the beginning, perhaps this led to neglect of many sanitary measures, of which this was one. Malaria, while not of a high death-rate, is doubtless responsible for many of the disabilities of the South where its elimination has been neglected. Dr. L. O. Howard has estimated that there are annually 3,000,000 cases in the United States, most of which are in the South, practically all of which are preventable.

PLAGUE

In plague we have a disease which has for centuries baffled sanitarians in their efforts to prevent its occurrence and spread. It was formerly believed to be communicated through the air and by the agency of fomites. The line of attack has been in the way of disinfection, with very inadequate results. It has been observed for many years that coincident with epidemics of plague, there was noticed a great mortality among the rats from an epizootic attack, and in 1894 Yerzin discovered that the *Bacillus pestis* was the cause of the attacks, and that the plague in man and rats was identical. By further investigation it was shown by Simonds in 1897 that the rat flea was the responsible transmitter of the disease. It is now generally admitted that the disease is primary in rats, and secondary in man, and by a process of elimination, the flea has been fixed as the intermediary. Then, as Dr. Richard H. Creel, who did so much work in San Francisco during the recent epidemic, says, the elimination of the rat is the only satisfactory method of getting rid of this disease.

It is well worth while to destroy all fleas possible, yet if those infesting the rat population escape, the effort will have had little effect in preventing the spread of plague. Major Morehead states that effort at rat destruction, (referring to such measures as trapping and poisoning, when those methods alone are used) is of doubtful value. The most efficient means thus far for the eradication has been that adopted by the Marine Hospital Service—building the rats out of homes; constructing in such way as to leave no nesting-places, keeping their number down by depriving them of food and breeding-places. The various experiments of developing a destructive micro-organism, or poisoning or trapping, have all been found inadequate.

THE RAT

The rat is a recognized carrier of a number of diseases. He is subject to leprosy, cancer, trichinosis, plague and other serious maladies. Rats are of absolutely no value and are now recognized by the whole world as a menace to health and as carriers of disease, not only from one community to another, but from one country to another, as they are noted travelers, especially by vessels. From their great propensity to travel, the rat, from his native home in China, has over run the entire world. To-day a serious problem is the elimination of the rat both as an economic, as well as a health measure.

HOOKWORM

The hookworm disease in the south has been investigated by Dr. Charles W. Stiles of the public Health and Marine-Hospital Service. Hookworm disease incapacitates for about one-quarter of the time; it is popularly called "the lazy disease," and is responsible for the so-called "poor white trash" of the South. It is curable by suitable drug treatment, and its elimination from the South will be of incalculable benefit.

MENTAL DISEASES

Mental diseases are on the increase, judging from the data of Dr. C. L. Dana of New York, who sees, during the past twenty-five years, an increase from one case in 450 persons to one in 300, a ratio which seems to be about the same in North America as in Europe, where similar conditions prevail. This increase is doubtless due largely to the increase of alcoholic and drug habits and syphilis. It is estimated by Sanborn that the number of insane in the United States exceeds 250,000.

These diseases alone need a method of prevention, for it is recognized that nine-tenths of the inmates of institutions are incurable.

The line of attack must be against the predominant causative agent, heredity, alcohol, syphilis and environment. More enlightment of the profession as to early symptoms and a better knowledge by the laity will add to the possibilities of prevention by early methods of treatment. The elimination of the procreation of the insane, the criminal, the idiotic, is a timely subject. Such methods have already been adopted in Indiana, Connecticut and Michigan. Indiana has gone even to the extent of prohibiting the marriage of all persons suffering from any transmissible disease. This subject should be taken up by our Faculty and its possibilities and feasibilities thrashed out, before the next general assembly. We are fortunate in having a phase of it presented to-night by Dr. Barker as a preliminary to its future study. With the consent of the faculty I shall appoint a special committee to give serious consideration for our future endorsement or rejection to vasectomy in its relation to eugenics.

DRUG HABITS

Closely associated with this doubtless one of the most serious medical problems of modern times is that of drug habits, which are far more prevalent in a variety of forms, than is usually realized. The commonest form of intoxication is alcoholic. This problem has been attacked largely along moral lines, and perhaps much good has been done, yet it seems to be one that should be approached from the medical side, and by educational methods as well.

The popular impression as to the harmlessness of alcohol in moderate quantities is erroneous. It is shown by scientists that the white corpuscles, the natural defenders, are weakened by its use. The alcoholic is more susceptible to the infectious diseases, because of a lowered resistance. There is hardly a disease to which it is not a contributory factor, nephritis, arteriosclerosis, cirrhosis of the liver and many others, besides all the possibilities of transmission to the offspring of various insanities and mental afflictions. From an economic view, alcoholism was found, on investigation by Prof. Henry W. Farman of Yale University, to be responsible for 25 per cent. of all cases of poverty coming under the eyes of the charity organizations, and 37 per cent. of all cases in alms houses. It was directly responsible for 31 per cent. of the criminals, and indirectly of 50 per cent.

The Massachusetts Bureau of Statistics in 1895 indicated that 84.41 per cent. of crime, 48 per cent. of pauperism and 35 per cent. of insanity were the results of alcoholism.

VENEREAL DISEASES

The effort on the part of societies for moral prophylaxis to reduce venereal diseases is meeting with a degree of success in the education of the young people, and will doubtless prove of enormous value in the reduction of the incidence of such diseases. And while we know full well that continence is compatible with health, yet we all realize that continence is not as generally practiced as might be hoped. The question has presented itself, is it not better to recognize this fact, in this fight against the black plague and to teach a method of prevention although it may appear as condoning an unlawful act.

From these few facts I have endeavored to show that there has been a gradual increase in longevity. From the knowledge of past achievements it is fair to assume that, with the possibility of medical discoveries, the number of diseases which will be added to the preventable list will certainly increase.

Such diseases as cancer, nephritis and diabetes, are increasing, and the real causative factors are not recognized. The problems are yet to be solved. Cancer, regarded as a fatal disease of unknown origin, is now engaging the attention of medical scientists, and while the facts thus far gathered are very vague and indefinite, yet with the great minds of the scientific world centered on it, the secrets of its cause must ultimately be ascertained.

GENERAL HEALTH PROBLEMS

The great problem of the future is the betterment of health by the education of the whole people as to its possibilities, teaching them the simple laws regarding food, drink, air and sleep. Our knowledge to-day is sufficient in itself, if it were employed, to increase human life at least fifteen years. Simply enacting laws will, in itself, be of little or no value, but such laws enacted and their value demonstrated to the people at large, preferably before their passage, will be beneficial just in proportion in which they are intelligently comprehended. The ideal time for teaching preventive medicine is in childhood; every school should provide some instruction along this line. The impressions of childhood are the effective, lasting ones.

The problems of health are not given great consideration by the usual adult. If he is an alcoholic, and has lived three-score years, this is attributed to the morning drink; if he were a smoker, tobacco has preserved him; if he were an abstainer, it is because of his abstemiousness. No one attributes it to a high degree of vitality; and here is the real problem in the fight against the usual diseases which decrease the breadth, and at the same time, while not in themselves fatal, lessen the length of life. The real problem, then, is to build up a constitution by prevention of diseases which we know to be preventable by sanitary means; to increase the efficiency of every individual by increasing his vital resistance, thereby establishing a bulwark against the inroads of many troubles which follow a depleted or lowered standard.

Another line of attack in the preventive measures should be an endeavor to prevent many diseases which lower the vitality, produce suffering and render soil suitable for the more serious maladies. Particularly is this true of influenza, and doubtless many of the nonfatal cases of infectious diseases in early childhood, which develop later into tuberculosis, nephritis or some other highly fatal disease.

PHYSICIAN AS AN ADVISER

Why should not the physician bear the relation of an adviser in health? Would it not be a wise and economical move on the part of the public to have an inspection of their vital resources at regular intervals, as they do of their physical resources? Is it not customary in mechanics to have a close watch kept over the machinery to prevent accidents and to maintain them in a high standard of efficiency? I believe that many diseases orginate in early childhood, causing much suffering in after-life, which could be arrested by such examination. The insidious attacks of many diseases of adult life, such as nephritis, diabetes and others, would be disclosed and suitable early treatment instituted, so as to prevent their extension. How often we are consulted about tuberculosis too late to be of much service, while an early examination would have discovered it in its incipiency.

How hopeless is cancer unless there is early recourse to operation! Examinations should be regularly made, often in early and late life, not so frequently in middle life. They should be suitably compensated for, and the physician in return should give a close study to diets, clothing and exercise, that each might be suitably individualized.

LEGISLATION

Along the line of health measures, which through the efforts of this state medical organization have become laws, I can make brief allusion to only a few. I would, indeed, be derelict in my duty were I not here to publicly congratulate the members of the General Assembly on their attitude on the health measures submitted to them for their consideration. The law-makers have realized that the public health is one of the most important assets of the state, and they have been guided by the views of the profession.

The presence of members of our profession on both sides of the house was of inestimable good in the cause of health, because of their ability to give lucid explanations to the lay members, and the profound confidence which their professional standing engendered.

The committees of this faculty on health legislation were indefatigable, and to them we owe a debt of gratitude for their untiring efforts.

The passage of the pure food law, drafted by the governor's commission, of which I was the chairman, was satisfactory to our faculty as represented by the committee. This law embraces every feature provided for in the faculty law to a most satisfactory bill, in that it includes a special proviso for standardizing disinfectants.

The passage of the bill for the state care of the insane places Maryland in the front rank of humanity, and corrects a condition which has been a discredit to the spirit of progress for which Maryland is noted. The measure will not only care for those who are incurably ill mentally, but will be the means of curing many early cases through supervision under trained specialists.

The enactment of the bills for the reorganization of the State Board of Health will systematize its work into bureaus, and thereby enable a closer watch to be kept on all the measures which protect the health of the people. Its appropriations will enable the bureaus to appoint specialists to watch over the departments, the water-supplies, sewerage, milk-supplies, and tuberculosis.

The passage of the midwifery bill as prepared by the committee, will be a great gain in the protection of mothers from incompetent and unintelligent women practicing midwifery. It will at the same time be the means of reducing enormously the percentage of blindness, for it has been demonstrated that nearly one-fourth of the cases in the Maryland blind schools have been in children delivered by midwives. The law was opposed by some who perhaps believed it impracticable, and for a time its fate was in the balance, when it reached the governor. His signature was secured only after the assurance of its practicability and value.

It, however, has brought it up squarely before the faculty, where they must endeavor to provide a way for its effective administration. We have now a law excellent in every detail; it demands that applicants to practice midwifery shall, to a degree, be instructed. At the present time we have no place for their instruction. The future committee on midwifery should endeavor to secure the cooperation of all hospitals with attached maternities, in order that such a course of instruction can be given. The Society for the Prevention of Blindness is fully alive to this immediate need, and will conjointly work with our faculty in this crusade against ignorance and disease.

With such results obtained by our faculty in its endeavor to secure legislation for the good of the people, demonstrating that we have secured the confidence of the law-makers, it only remains for us to continue our campaign of education in matters of health, and to demonstrate our knowledge of disease and that will enable us to secure all the legislation needed for the future.

At the present time we must realize that measures which are inimical to the progress and dignity of the profession are often times introduced for mercenary purposes, as in the recent optometry bill, or through the efforts of the misguided or neurotic, as in the antivaccination bill, both of which measures were defeated.

ANIMAL EXPERIMENTATION

Such legislative efforts should remind us that it is incumbent on us to fully enlighten the public as to the true significance of vivisection, as there is a wave of opposition to its practice, sweeping over the country, fostered by deluded and misguided individuals, with their hysterical attacks of falsehood and calumny. Their grotesque and misleading exhibits all tend so to arouse the sympathy of the people as to inflame them to a radical and erroneous legislation. I believe it wise to take some heed of this mild form of insanity, which would arrest absolutely, the future advance of medicine.

Perhaps a small committee of hospital or college men to explain the means, significance and humane methods of experimentation on lower animals to the public by lectures, or through the daily press, would educate the people sufficiently, and offset the ravings of those so perverted as to believe that animal life is worth more than human, yet they themselves may not be vegetarians.

NATIONAL DEPARTMENT OF HEALTH

To correlate all these forces working for the uplift of man, to increase his health and thereby his happiness, there can be no greater assistance than to elevate the profession to the highest honor to which it is entitled, and there is no more potent way to increase its field of usefulness, to engender for it the confidence of the people, to spread the gospel of health, to discredit fads and quackism, than to harmonize all departments under a national department of health. For this every physician, and every county and state society, and finally the national association should strive.

PROMISE FOR THE FUTURE

Thus, when we look down the long vista of time and see one disease after another mastered by the science of medicine, and recall those reassuring words of Charles Darwin, "It is those who know little, and not those who know much, who so positively assert that this or that problem will never be solved." I feel, indeed, that the future holds many promises for the betterment of the human race.

330 North Charles Street.

Positive Tuberculin Tests in Syphilitics.—Nicolas and Favre state that they obtained a positive response to the von Pirquet cutaneous and to the Mantoux intradermal tuberculin tests in 75 and 93 per cent. respectively of 28 and 47 syphilitics free from any suspicion of tuberculosis. This proportion of positive responses is as high as is obtained among the *confirmed* tuberculous, and consequently, they assert, neither of these diagnostic tests is able to differentiate tuberculosis from syphilis.—*Bull. S* [illegible] *d. des Hôp.*, March 17, 1910, page 239.

THE EFFECT OF STOVAIN ON THE NERVOUS SYSTEM*

WILLIAM G. SPILLER, M.D.,
AND
SAMUEL LEOPOLD, M.D.
PHILADELPHIA

As stovain produces temporary anesthesia, it occurred to us that repeated injections of the drug probably would produce anesthesia of gradually increasing duration until finally we might obtain a persisting loss of sensation, which would be the result of organic change. Whether the same may be said of any other drug has not as yet been determined. We desired to ascertain *whether a systemic degeneration of the posterior roots and their continuation in the posterior columns of the cord is the common result of the repeated use of stovain. It* was important, moreover, to determine whether *the* paralysis that occurs in stovain anesthesia is of a motor or sensory type, i. e., whether it is produced by changes in the peripheral motor neurons, or is the result of abolition of all afferent impulses which normally pass over the posterior roots. Reflex action and all recognition of tonicity or relaxation of the limbs, and necessarily of the position of the limbs, are lost if all peripheral afferent impulses are cut off.

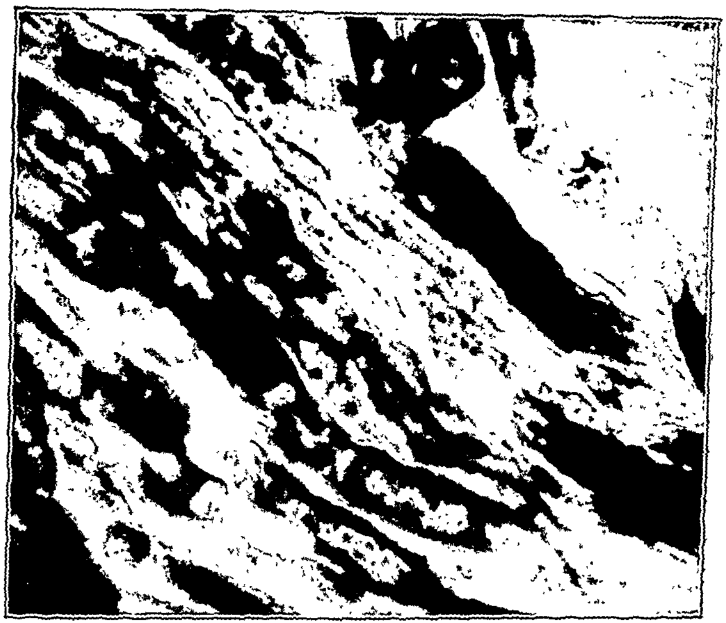

Fig. 1.—Section through a lower spinal ganglion, showing degeneration as small black dots, in the nerve fibers.

Some investigations regarding the effects of stovain on the nervous system have been made, but they are not numerous, and in certain respects the results do not fully correspond with those obtained by us.

Spielmeyer found changes in the cells of the anterior horns from stovain poisoning in man, the dog and the ape, of the character of reaction at distance. In man the cells of the spinal ganglia were not affected. He regards the cellular changes as primary notwithstanding their character. The alteration was seen only in scattered cells. He has never seen degeneration of the white matter in the cord of man; at most he has found changes in the nerve cells of retrograde type. He has had five cases, three in apes and two in dogs, in which the degeneration was confined to posterior root fibers and their continuation in the cord, so that it would appear that stovain degeneration may at times be confined to the posterior roots. He seems to have depended on the Marchi method chiefly, and there is no mention of teasing of nerve fibers and of staining them in the fresh state. The degeneration affected the short fibers of the posterior roots, the reflex collaterals more than it did the long fibers. The stovain, he thinks, attacks the extramedullary portion of the posterior roots, and the degeneration of the intramedullary portion is secondary to this. This process differs from tabes, in Spielmeyer's opinion, because in tabes the degeneration begins in the intramedullary portion of the posterior roots.

---

* From the Department of Neurology and the Laboratory of Neuropathology in the University of Pennsylvania.

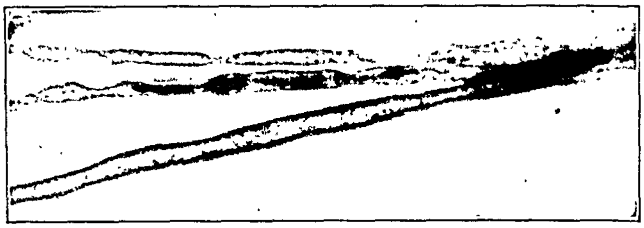

Fig. 2.—Fibers of a lumbar posterior root teased and stained with osmic acid, showing degeneration.

Spielmeyer states that the posterior roots outside the dural sac were intact, in contrast to the greatly degenerated cauda equina within the dural canal. In the spinal ganglia not only the peripheral but also the central nerve fibers appeared normal by osmic acid stain, so that changes were not noticed in the posterior roots until the roots had entered the intradural space and come into direct contact with the stovain. The degeneration of the anterior roots, in the cases in which the process was more extensive and was not confined to the posterior roots, began where the anterior roots made their exit from the cord, and the intramedullary portions of the anterior roots were intact. In both the posterior and anterior roots the products of disintegration were soon absorbed. The anterior roots were degenerated secondarily also in the portion beyond the dural sac, so that the anterior root in contact with a spinal ganglion frequently appeared degenerated while the ganglion and its nerve fibers at each end were intact. In ten experimental cases that Spielmeyer examined the posterior roots were predominantly or exclusively affected; he therefore concludes that stovain selects especially the posterior roots. He states that scar formation or inflammation plays no part; also that the degree of degeneration is not proportional to the amount of stovain used.

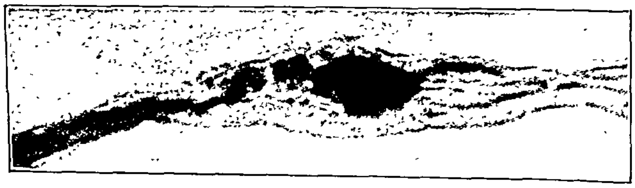

Fig. 3.—Fibers of a lumbar anterior root showing larger masses of degenerated myalin.

The changes in the cells of the anterior horns he found in man, as indicated in his illustrations, were pronounced. He found in animals swelling, displacement of the nucleus, and chromatolysis in the cells of the spinal ganglia. He thinks that the sensory and motor disturbances that occur after stovain anesthesia in man may be caused by similar changes in the spinal roots and in the periphery of the spinal cord, as are the temporary ocular muscle palsies from cellular changes; but pathologic studies are wanting in these cases.

Root degeneration has not been found in man, although Spielmeyer[1] studied the specimens from sixteen cases. In half of these cases death occurred too soon to permit the Marchi method to be employed. These findings are remarkable, as root degeneration was obtained in all his injected animals. The symptoms following injections in apes were not very positive. In dogs he observed temporary paraplegia with disturbance of sensation and of micturition.

The investigation as conducted by van Lier[2] and Wossidlo,[3] showed that the cellular changes were temporary. Wossidlo found, after injection, paresis of the posterior limbs, restlessness, frequent respiration and clonic spasm of the posterior limbs. Usually these symptoms disappeared after artificial respiration. In some instances opisthotonos occurred. The lumbar region was examined one to twenty-four hours after the injection, and he found chromatolysis and swelling of the cell. When stovain was used the most pronounced changes were seen after one hour. Scarcely any normal cells were found in the anterior horns. The changes were more pronounced after two hours, and improvement was noticed in the cellular condition after six hours. The cells were normal after twenty-four hours. Van Lier's findings were similar. They used rabbits. Wossidlo concluded that tropacocain was less dangerous than stovain or novocain and that changes occurred in the cells in lumbar anesthesia, but that they were not serious enough to prevent the use of drugs in this method.

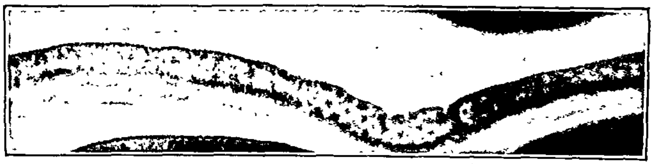

Fig. 4.—Fibers of a peripheral nerve from a hind limb, showing degeneration. In many fibers the degeneration was more advanced.

Rehn could not demonstrate any changes in the cells of the anterior horns until after three days; then they were found in the lumbar, thoracic and cervical regions, and yet only a few cells in any one section were altered. The alteration began at the periphery of the cell, and the nucleus became peripheral. Animals that had lived ten to twenty-one days showed by the Marchi method, degeneration in the entire periphery of the cord and in the entire posterior columns, in the latter apparently, systemic in character. Only cells in the anterior horns were affected; sensory cells were intact. Rehn's report[4] is of findings obtained by Klose and Vogt.

The technic of our experiments consisted in performing lumbar puncture on five dogs with careful avoidance of infection. The stovain solution used on Dogs D and E was boiled. The dose of each stovain injection varied from 0.05 gm. to 2 gm. and except in Dogs A and B, in each of which only one injection was given, the injections were usually at intervals of two to three days.

The symptoms may be divided into the temporary and the permanent. The temporary consisted of flaccid paralysis and complete or partial sensory loss. The hind limbs showed flaccid paralysis, while the entire body frequently showed the loss of sensation, implicating even the ear. Bladder and rectal control was lost, and the tendon reflexes were either diminished or absent. These symptoms occurred immediately or several minutes after the injection was given, and persisted from one to several hours.

The permanent symptoms consisted of ataxia, decreased sensation, and, in Dog E, loss of patellar reflex. The symptoms became permanent after the third injection, remaining until the end of the experiment. The ataxia was recognized by the irregular gait, and the tendency to stand with the hind legs well apart, and the peripheral part of the hind limbs well on the ground.

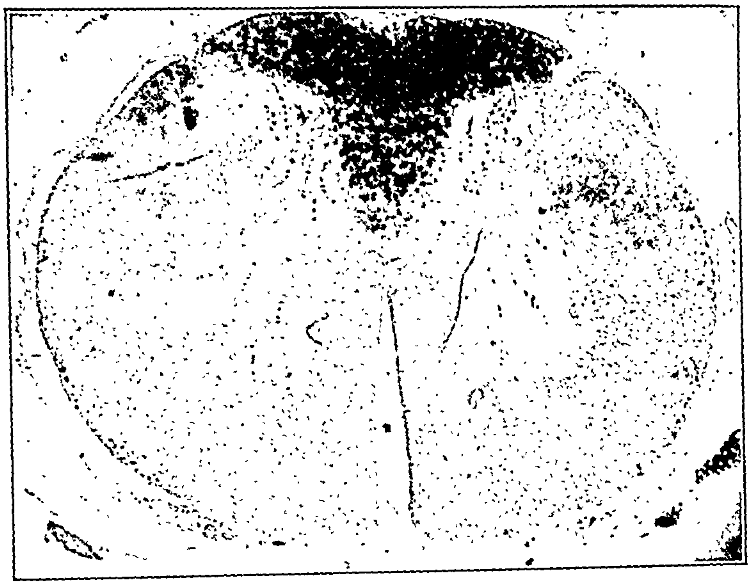

Fig. 5.—Section through the lumbar region (from retouched photograph) showing intense degeneration of the posterior columns.

Sensory disturbances were demonstrated by the clip test. Dog A lived one hour after the injection, Dog B four hours, Dog C seventeen days, Dog D 2 months and Dog E forty-two days. The investigations have not been completed, but the results obtained are interesting.

The alterations of the cells of the anterior horns were not important in any of the five dogs; in some slight central chromatolysis, and displacement and swelling of the nucleus were found. Dog D showed degeneration in the columns of Goll, more marked on one side, but dog E gave the most important results, and the following description is from the sections obtained in this case.

LUMBAR REGION

Axis cylinders in the periphery of the anterolateral and posterior columns were found here and there considerably swollen; some were of large size; swollen axis cylinders were seen in the root entrance zones of the posterior columns, but otherwise not in the posterior columns except near the periphery. A moderate degree of cellular reaction to the stovain was detected in the pia and roots of the cord in the form of round cell infiltration, but never as cells of polynuclear type. This is not a surprising finding and resembles what is seen in tabes. One would expect some cellular reaction to a poison affecting the nervous system as does stovain. A very slight perivascular round-cell infiltration was seen here and there in the cord; it was so slight as to be of no importance, and its existence was disputable. The swelling of the axis cylinders in the anterior and posterior roots was very distinct, and the swelling affected most of these axis cylinders. One forms the impression that the axis cylinders were more swollen in the anterior than in the posterior roots.

The posterior columns in the lumbar region were degenerated, as shown by the Marchi method, throughout a transverse section, but much less so in the ventral zones. The reflex collaterals were also much degenerated, and the degenerated fibers could be traced forward into the anterior horns. Small black dots were found along some of the anterior roots within the spinal cord, and this finding indicates a moderate amount of degeneration here. A slight degeneration was found by the Marchi method along the periphery in the anterolateral columns; it was far less intense than in the posterior columns. In the thoracic region the degeneration of the posterior columns was confined to the columns of Goll; the columns of Burdach seemed to be intact. The degeneration of the anterolateral columns in the thoracic region was insignificant. The lumbar sections were taken fully one and a half to two inches above the point of injection.

Anterior and posterior roots taken between the dural cavity and the posterior ganglia were teased in the fresh state and stained with a 1 per cent. aqueous solution of osmic acid. They presented considerable degeneration, chiefly in the form of minute black granules within the neurilemma sheaths, and the degeneration was more advanced in the anterior roots. One could not conclude from this finding that stovain affects the anterior roots more than the posterior; rather the finding would seem to imply that, the roots having been affected by the stovain within the dural sac, secondary degeneration would be found in the portion of the anterior roots examined, and retrograde degeneration in the portion of the posterior roots examined. Nerve roots taken from within the interior of the dural canal unfortunately were not examined by this method.

The nerve fibers in one of the lower spinal ganglia, placed in the fresh state in 1 per cent. osmic acid solution, showed intense degeneration of the fine granular variety. The cells of the ganglion presented little degeneration.

A nerve taken from the hind leg appeared intensely degenerated, when placed in the fresh state in osmic acid.

The method of studying nerve fibers in the fresh state with osmic acid, employed by us, does not appear to have been used in previous studies with stovain injections; it has given most satisfactory results. It is probably because of the employment of this method that we have obtained distinct degeneration in the posterior roots between the dural cavity and the ganglion as well as in the ganglion itself—findings not obtained by Spielmeyer. Our results differ from those obtained by others in the absence of important alteration of the cells of the anterior horns, although we employed the thionin stain for examining these cells.

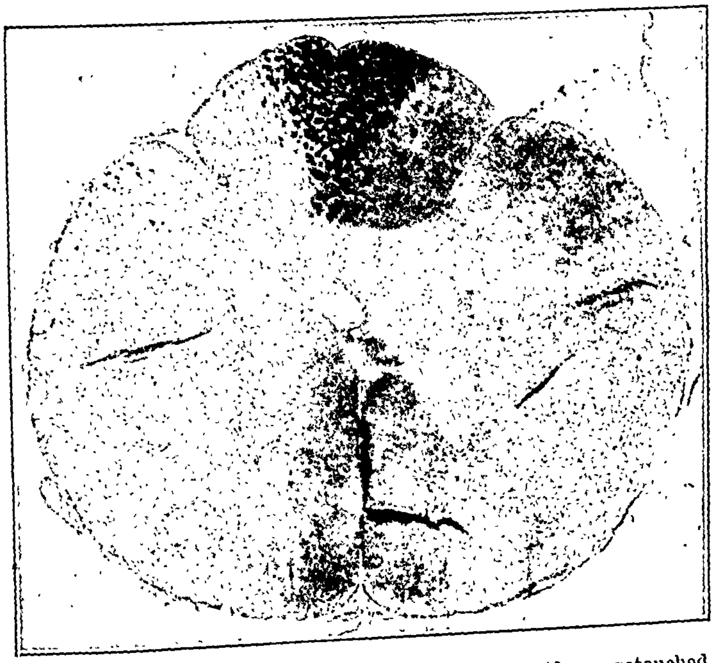

Fig. 6.—Section through the thoracic region (from retouched photograph) showing degeneration confined to the columns of Goll.

It seems clearly demonstrated that stovain affects especially the anterior and posterior roots; the degeneration of posterior root fibers in our sections was intense; what is worthy of note, the degeneration of the intramedullary portion of the lumbar and sacral posterior root fibers in the thoracic region was still intense. The posterior thoracic roots were unaffected. Stovain evidently also causes slight degeneration in the periphery of the anterolateral columns, but has less effect here than on the nerve roots.

These lesions obtained by us could not have been produced by the trauma of the needle, as the sections of the lumbar region examined were one and a half to two inches above the point of injection, and yet the posterior and anterior roots were greatly degenerated.

It would be unwarranted to apply these findings too strictly to man, as no grave changes have been found as yet in the human spinal cord. At most our findings would show that repeated injections of stovain might be injurious, and would make one cautious in employing several injections within a short time in the same subject. We do not know whether stovain has more effect on the nervous system of the dog than on that of man.

Fig. 7.—One of the dogs (Dog D) experimented on, showing ataxia of hind legs.

The investigations show further that the paralysis produced by stovain is of the motor type, as the anterior roots were greatly degenerated.

NOTE ON CORRECTING THE PROOF.—Investigations made with magnesium sulphate have not given clinical results similar to those obtained with stovain. Four injections of ten drops each of a saturated solution of this drug have been made into the dural cavity of a dog, extending over the period from March 31 to the present time. No ataxia has occurred, the dog walks with the hind legs close together, and the reflexes are normal, but sensation of the hind legs seems to be slightly diminished.

We are indebted to Dr. Allen J. Smith for the photographs.

1906 Chestnut Street—1632 North Franklin Street.

Campaign Against Uterine Cancer in the Argentine Republic.—The *Sociedad de Obstetricia y Ginecologia* of Buenos Aires is sending out a blank circular to the general practitioners and gynecologists throughout the country asking for data in regard to the number of patients with uterine cancer that were in their charge during 1909. Details are asked in regard to the operability, operations, results of operation: survival for less than one year, less than 2, 3, 4, 5 or more years; deaths from the operation or complications, from other affections, or the ultimate outcome not known. The number of deaths from cancer of the genital organs in Buenos Aires amounted to 31 per cent. of the total female mortality from affections of the genitourinary apparatus during 1908. The appeal is published in the *Semana Medica*, 1910, xvii, 96.

FRACTURE OF THE PATELLA

THE OPERATION OF CHOICE*

E. P. MAGRUDER, A.M., M.D.
Assistant Professor of Surgery, Georgetown University; Associate in Surgery, Emergency Hospital
WASHINGTON, D. C.

TYPES OF FRACTURE

Before the birth of antiseptic surgery Severino, the brilliant Neapolitan surgeon, in 1598 performed the first open-suture operation on a fractured patella. His patient died. Three hundred years later, Lord Lister, the father of antiseptic surgery, repeated the same operation. His patient lived. This bit of history is conclusive of little but suggestive of much.

Most frequent between the thirtieth and fiftieth year, rare under the twentieth, fracture of the patella is scarcely ever seen in children under 10. Eighty-eight per cent. of the cases are found in men. Of all bone fractures that of the patella represents 1.4 per cent. The decade between 40 and 50 years yields the highest number of cases.

We may distinguish the open and the closed types, the transverse and the longitudinal, the oblique, the stellate, and the comminuted. As many as nine fragments have been found in this fracture. Avulsions of the tip and of the basal margin are reported.

The line of division is central, or more commonly below rather than above the middle of the bone. The prepatellar fibrous tear may be above or below the line of bony separation. Often the lower end is ruptured; rarely the upper. Twofold and threefold transverse fractures are reported, the latter the result of refracture. In the compound fracture the T or Y-type is occasionally seen. The longitudinal form is rare. Comminution is frequent in direct violence, which constitutes 80 per cent. of all fractures of this bone. A fissure fracture may extend to the cartilage without involving it. The fracture may be simply subaponeurotic, with neither displacement nor other symptoms and discernible only through the *x*-ray.

Associated injuries are common and very significant. The dense ligamental fascia over the bone is almost always ruptured, the tear extending into the capsule, internally into the reinforcing tendinous fibers of the vastus internus and externally into the fascia lata—the extensor lateral expansion of the leg. With this condition the prepatellar bursa may be contused and there may be an effusion of blood into the joint.

The line of the ruptured aponeurosis is not always identical with that of the fractured bone. More frequently it lies above or below it, an intervening tab preventing bony union. This was the clinical observation of Macewen and König, afterward verified by Hoffa in his experiments on the cadaver. Barlöcker reported 28 cases with operation, in every one of which he found the fibroperiosteal intervention.

ETIOLOGY

The condition is usually the result of a fall, a blow, or a gunshot wound. Bähr and Rossi's statistics show that the effect of muscular contraction has been overrated. This variety of fracture can occur only when the knee is extended. Rossi held that ruptures of the quadriceps tendon or of the ligamentum patellæ was in-

ing even the ear. Bladder and rectal control was lost, and the tendon reflexes were either diminished or absent. These symptoms occurred immediately or several minutes after the injection was given, and persisted from one to several hours.

The permanent symptoms consisted of ataxia, decreased sensation, and, in Dog E, loss of patellar reflex. The symptoms became permanent after the third injection, remaining until the end of the experiment. The ataxia was recognized by the irregular gait, and the tendency to stand with the hind legs well apart, and the peripheral part of the hind limbs well on the ground.

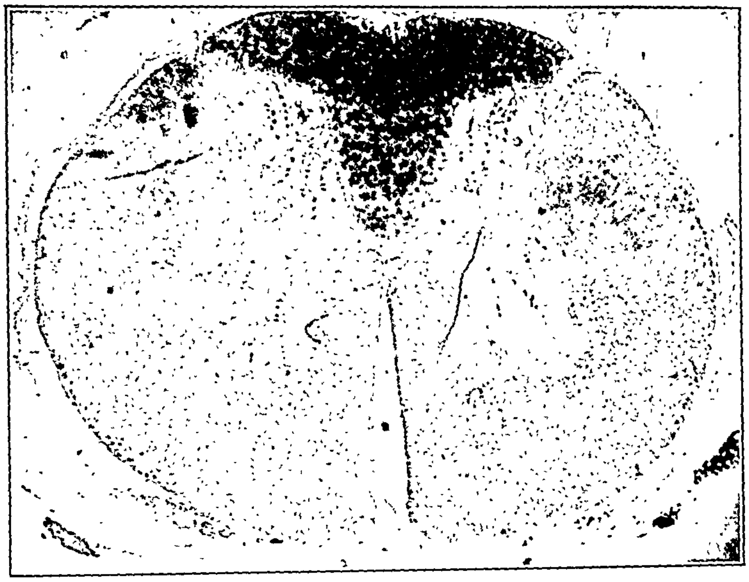

Fig. 5.—Section through the lumbar region (from retouched photograph) showing intense degeneration of the posterior columns.

Sensory disturbances were demonstrated by the clip test. Dog A lived one hour after the injection, Dog B four hours, Dog C seventeen days, Dog D 2 months and Dog E forty-two days. The investigations have not been completed, but the results obtained are interesting.

The alterations of the cells of the anterior horns were not important in any of the five dogs; in some slight central chromatolysis, and displacement and swelling of the nucleus were found. Dog D showed degeneration in the columns of Goll, more marked on one side, but dog E gave the most important results, and the following description is from the sections obtained in this case.

LUMBAR REGION

Axis cylinders in the periphery of the anterolateral and posterior columns were found here and there considerably swollen; some were of large size; swollen axis cylinders were seen in the root entrance zones of the posterior columns, but otherwise not in the posterior columns except near the periphery. A moderate degree of cellular reaction to the stovain was detected in the pia and roots of the cord in the form of round cell infiltration, but never as cells of polynuclear type. This is not a surprising finding and resembles what is seen in tabes. One would expect some cellular reaction to a poison affecting the nervous system as does stovain. A very slight perivascular round-cell infiltration was seen here and there in the cord; it was so slight as to be of no importance, and its existence was disputable. The swelling of the axis cylinders in the anterior and posterior roots was very distinct, and the swelling affected most of these axis cylinders. One forms the impression that the axis cylinders were more swollen in the anterior than in the posterior roots.

The posterior columns in the lumbar region were degenerated, as shown by the Marchi method, throughout a transverse section, but much less so in the ventral zones. The reflex collaterals were also much degenerated, and the degenerated fibers could be traced forward into the anterior horns. Small black dots were found along some of the anterior roots within the spinal cord, and this finding indicates a moderate amount of degeneration here. A slight degeneration was found by the Marchi method along the periphery in the anterolateral columns; it was far less intense than in the posterior columns. In the thoracic region the degeneration of the posterior columns was confined to the columns of Goll; the columns of Burdach seemed to be intact. The degeneration of the anterolateral columns in the thoracic region was insignificant. The lumbar sections were taken fully one and a half to two inches above the point of injection.

Anterior and posterior roots taken between the dural cavity and the posterior ganglia were teased in the fresh state and stained with a 1 per cent. aqueous solution of osmic acid. They presented considerable degeneration, chiefly in the form of minute black granules within the neurilemma sheaths, and the degeneration was more advanced in the anterior roots. One could not conclude from this finding that stovain affects the anterior roots more than the posterior; rather the finding would seem to imply that, the roots having been affected by the stovain within the dural sac, secondary degeneration would be found in the portion of the anterior roots examined, and retrograde degeneration in the portion of the posterior roots examined. Nerve roots taken from within the interior of the dural canal unfortunately were not examined by this method.

The nerve fibers in one of the lower spinal ganglia, placed in the fresh state in 1 per cent. osmic acid solution, showed intense degeneration of the fine granular variety. The cells of the ganglion presented little degeneration.

A nerve taken from the hind leg appeared intensely degenerated, when placed in the fresh state in osmic acid.

The method of studying nerve fibers in the fresh state with osmic acid, employed by us, does not appear to have been used in previous studies with stovain injections; it has given most satisfactory results. It is probably because of the employment of this method that we have obtained distinct degeneration in the posterior roots between the dural cavity and the ganglion as well as in the ganglion itself—findings not obtained by Spielmeyer. Our results differ from those obtained by others in the absence of important alteration of the cells of the anterior horns, although we employed the thionin stain for examining these cells.

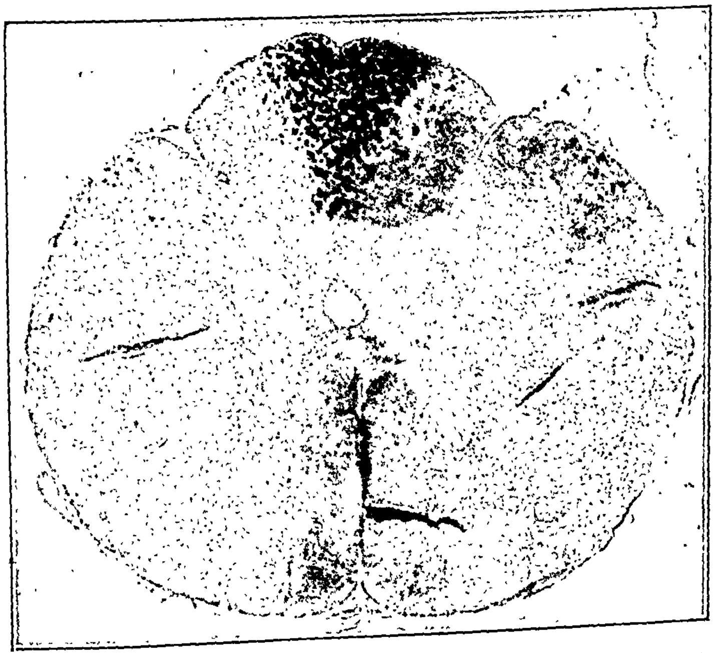

Fig. 6.—Section through the thoracic region (from retouched photograph) showing degeneration confined to the columns of Goll.

It seems clearly demonstrated that stovain affects especially the anterior and posterior roots; the degeneration of posterior root fibers in our sections was intense; what is worthy of note, the degeneration of the intramewithstand his weight. It is best to continue this protection and support to the knee for six months, following passive and active motion at the end of the sixth week. Crutches are discarded at eight weeks, the cane and removable splint at six months. Due care during all this time should be exercised to avoid falls, sudden and jerking movements to prevent refracture.

Hemorrhage, if imminent, may be retarded, if not prevented, by wet compress, bandage, and elevation in the Volkmann splint, to relax the extensor; or the region of the knee may be firmly bandaged from below upward with a rubber elastic bandage and put on a well-padded posterior splint; unmolested for forty-eight hours. If there is much distention about the joint Schede aspirates.

If open suture is inexpedient Bardenheuer and Lichtenauer use weight extension, 30 to 40 pounds, to relax the extensors, continuing this from four to six weeks until union is accomplished.

Fibrous union often occurs with a limited extension and flexion, as is seen in the protracted fixation of a plaster splint, with such sequelæ as shrinkage of the capsule, adhesions, and atrophy of the quadricipital group.

Where the lateral expansions have not been involved, on the other hand, only a small amount of functional impairment may follow the fibrous cicatrix.

Metzger, Tilanus, and others, have recommended early massage and mobilization. Tapotement and kneading are begun during the first forty-eight hours following the injury, directed to the joint as well as to the muscles of the leg and thigh—the fragments held the while by an assistant. The upward stroke aids in blood resorption. Individual cases are helped by the faradic current. Under this treatment passive motion is begun at the end of the first week; the patient is allowed up at the end of the second, when light exercise is instituted; first walking on crutches, then with a cane; finally at the end of the sixth week, he is discharged.

The extreme methods of zum Busch and of Kraske are not to be recommended. For as observed by Soutter, the value of massage is unquestionably overestimated. True, it does aid resorption of intra-articular, peri-articular and intramuscular diffusion. Increase and preservation of muscular tone can only be accomplished through exercise. If the reserve extensors are ruptured entirely or even for the greater part, loss of function leads to inevitable atrophy of the extensors in spite of ample massage and early exercise. Further, the muscular contraction under these circumstances separates more widely the fragments and adds to the labor of operative procedure later on.

Aspiration of the blood is unsatisfactory because of the debris, clots, etc., and is attended with the danger of infection.

To despair of bony union at the outset is for the physician to acknowledge a misplaced confidence on the part of the patient. On the contrary it would seem advisable in most cases to attempt exact coaptation and ossific union by the direct method, and to prevent ill results by instituting muscular massage at the beginning, followed by passive motion during the first week, and active motion after the second.

The Operative Method

Trendelenburg recommended a delay of eight days in the operation with a view to determine the chances of recovery without it and to allow for subsidence of the swelling. If open suture is clearly indicated why should we delay twenty-four hours unless it be to impugn our present-day technic? Do we not get the patient out just eight days earlier by an eight days' earlier operation?

As a rule the operation should be as early as possible.

Various incisions are in use, such as the transverse— the longitudinal |, the semilunar with convexity upward ∩, the semilunar with convexity downward ∪, the semilunar with convexity inward), the semilunar with convexity outward (, and modifications of all six of these.

Some use drainage, some do not. Intra-articular drainage except in plainly septic cases is to be condemned.

Some irrigate the articulation, some use the dry sponge, some do neither. The solutions used are bichlorid, 1:1500; phenol in various strengths, physiologic salt solution, and sterile hot water.

For suturing both hard and soft structures, materials of both absorbable and non-absorbable character are in use. Some use pegs. Most common of the absorbable sutures may be mentioned plain and chromic catgut, and kangaroo tendon; of the non-absorbable, silver wire, iron wire, aluminum bronze wire, copper wire, Pagenstecher thread and heavy silk.

Men of equal surgical skill and ability differ widely as to their methods of operation. What then is the best method? The answer to this question should be based not only on theoretical grounds but on the study of the pathologic conditions found and on the final results.

When operation is clearly indicated I believe it done best when done most quickly. What is the operation of choice for fracture of the patella? Having observed and followed up a number of cases I would humbly suggest the following as the operation of choice:

The time should be as soon as possible after the injury; the operation should be done under ether anesthesia, with the strictest aseptic technic, gloves and exclusively instrumental handling; the semilunar incision with convexity downward should be used, commencing a little above the fracture line internally and carrying the oval incision downward and below the tibial tubercle and up on the external lateral surface to a point opposite that of the beginning. The flap should be turned back on itself to expose both the fractured bone and the ruptured aponeuroses, and the interposed fibroperiosteum removed. The joint should be thoroughly and completely irrigated and all clots and liquid blood removed with hot sterile physiologic salt solution (or 1:5000 bichlorid, followed by sterile water, if there is the slightest suspicion of infection). Stout bone-forceps now hold steadily the fragments while the bone-drill, directed obliquely through two thirds its thickness and always avoiding the joint, is passed through each fragment, the holes in the upper and lower fragments being in exact alignment and always as few as possible. Both points of entrance and points of exit in each bone should correspond with those of the other. The drill-holes throughout are from without inward and, as stated, always as few as circumstances will permit, and just large enough to accommodate wire of the smallest diameter practicable. All drilling is completed before inserting the wire. The wires, preferably silver or iron, passed, they are grasped with blunt-nosed forceps, and while the assistant carefully approximates the margins, the surgeon tightly twists the wires three or four times on themselves, cuts them off a quarter-inch long, bends them down and buries them beneath the fibroperiosteum, which is then sutured above. If the fibro-periosteum be interposed and is ragged when drawn out, its edges should be neatly trimmed of roughened projections, carefully coapted after the bone is sutured, and stitched, first with interrupted chromic catgut and reinforced with a continuous suture of the same material. The rent in the capsule, so common on either side of the fractured bone, is repaired with equal carefulness and with the same suture material. An additional continuous suture of fine chromic gut is used to repair the fibrous covering of the patella incised in raising the oval flap. The skin flap is then sutured with three light silkworm-gut sutures, the first in the center at the tibial tubercle, followed by one each at the halfway point on the ascending lateral line of incision, and this in turn followed by a continuous fine plain catgut suture of the entire skin wound. No drainage is used; a moist bichlorid compress over the site of the wound is followed by a sheet-cotton bandage from toes to middle thigh, and over this a light removable split plaster mold, applied with the limb in complete extension, in which it is kept, heel slightly elevated, with as little interference as possible for two weeks. Then massage is used, passive motion, light exercise; walking on crutches, then with a cane, and then with mold splint alone; and finally, at the end of the sixth week, without any support whatever, the patient is discharged as cured.

In support of this method the following points of advantage may be cited:

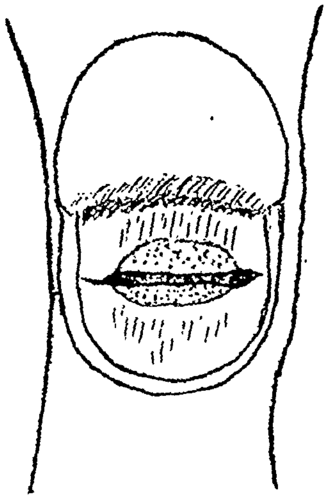

Fig. 1.—Incision of the author's choice.

There is no loss of time; the safest anesthetic is used; absolute exposure of the entire field of injury is obtained, especially of those most important structures, the lateral expansions; the articulation is made perfectly clean with a non-irritating solution; a suture too small to excite irritation is used and one that is non-absorbable, therefore effective to hold till union has had abundant time to take place; there is no necessity for post-operative drainage; activity is too late to fear fracture recurrence, too early to invite atrophy; and though of exceptional occurrence, a tear of the accessory ligaments with no separation of the bony fragments noticeable on inspection or palpation would be exposed. Immediate operation admits of union by first intention.

Fibrous union leaves a weakness, an uncertainty, an instability, a timidity on the part of the patient, frequently resulting in his falling, which in turn induces refracture. Absolute functional recovery in fibrous union is exceptional.

Small incisions fail freely to expose the operative field, render difficult the cleansing of the joint and the repair of the lateral capsular and aponeurotic tears.

The vertical incision leaves a cicatrix exposed to pressure on kneeling and remains tender, limits the field of operation, makes difficult the passage of wires; the rents in the lateral expansion are not easily reached; and manipulation of the fragments is difficult.

The transverse incision is open to the objection that often the osseous and cutaneous cicatrices correspond, increasing the facility for compound refraction; infection, too, passes readily from the outer to the inner wound; a stitch abscess may produce a septic arthritis; drainage is difficult.

A flap with convexity downward has a better arterial and nerve supply; it admits most easily of drainage.

Irritating antiseptic irrigations, such as phenol, bichlorid, etc., are injurious to the joint endothelium, lower its resistance to infection, and predispose to inflammation. Physiologic salt solution accomplishes the same purpose as the irritants without any of their disadvantages. Dry sponging, in cases in which the parts may readily be reached, is preferable to either.

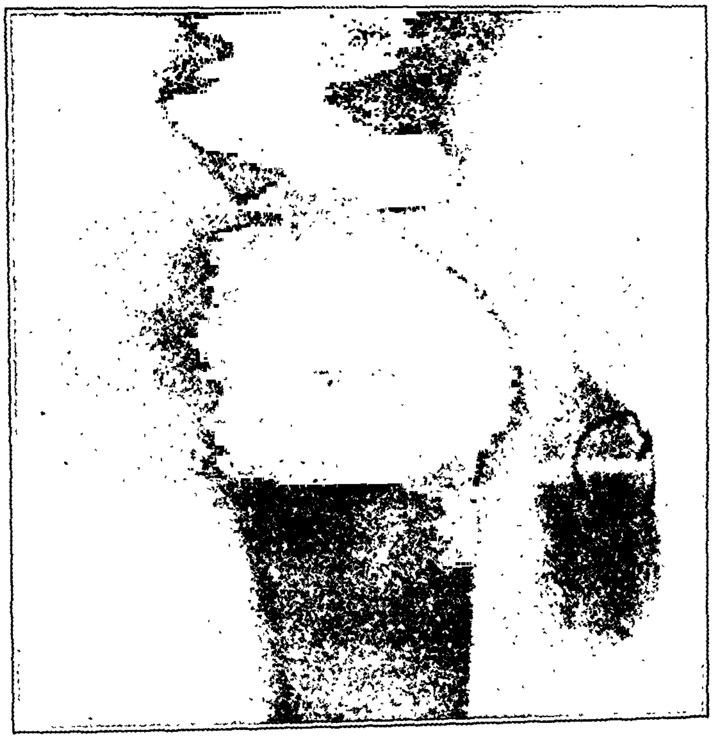

Fig. 2.—Author's method of wiring. Joint radiographed day after operation by Dr. T. A. Groover; the wire does not enter the joint; its head is turned down and buried beneath the fibroperiosteum.

Patient (for whom author is indebted to Dr. George Tully Vaughan), A. H., aged 20, male; on the afternoon of July 14, 1909, while running, stumbled, fell to the ground, and was unable to assume the upright position afterward. He was brought to the Emergency Hospital, where examination showed transverse fracture of patella, fragmentary separation 2 inches, showing considerable involvement of the lateral expansions; knee-joint much swollen, painful, and distended with blood; extension lost; wide lateral movements of the fragments. Operation next morning—open method, wired—patient discharged, cured, Aug. 21, 1909. The technic, operative and post-operative, was that described herein.

The question may be asked, when the open operation is indicated, when contraindicated. It is indicated in fractures productive of functional joint impairment, such as those in which fragments have entered the articulation; in the one-legged, in whom ankylosis following fracture would produce complete inability to walk; in bilateral fracture of the patella; in refractures; in ununited fractures, the result of attenuated fibrous union or faulty position; in unrepaired aponeurotic laceration.

The open method may be confidently recommended in the presence of an aseptic environment, a competent surgeon, safe suture material, favorable physical condition of the patient, bad position of fragments, in all compound fractures, all comminuted fractures, in profuse intra-articular effusion, hemorrhagic or inflammatory, in interposition of the fibroperiosteal tissues.

In compound fracture the necessity for open suture is self-evident; so, too, if bandaging fails, and also in the presence of a weak, extensile fibrous repair.

When is it contraindicated? In the diabetic, in advanced tuberculous disease, in chronic cardiac, renal, or hepatic disease, in longitudinal fractures of the closed type and without displacement, in simple subaponeurotic or incomplete fractures, and those in which separation of the fragments is so slight as to be barely detectible.

Malgaigne's clamp and Trélat's modification thereof are to-day merely historic.

To the subcutaneous work of von Volkmann, in 1868, of the earlier labors of Kocher, Ceci, Heusner, Butcher, Barker, and the rest, I am compelled to make the same objection as to every other subcutaneous method, namely, that the interposition of the periosteum and the lateral tears are disregarded; further, that the joint may be opened. The only point in its favor is the fact that it was the forerunner of the direct suture method.

As between Lister's transverse incision at the fracture line, and a longitudinal or transverse incision not in line with the fracture, the latter is to be preferred.

Strict asepsis is the first requisite and the last indispensable point in the technic of the open operation. Nowhere are results better with it; nowhere worse without it. An infected arthrotomy is more to be dreaded than an infected laparotomy. Palpation with a gloved hand should be reduced to the minimum. If possible the operation should be entirely instrumental.

If the quadriceps is much retracted and the attempt to approximate the fragments fails when the thigh is flexed, the muscles fully relaxed, and the knee extended, then a plastic operation may be done by division of the ligamentum patellæ or the quadriceps.

Where separation is considerable, Rosenberger, Helferich, Wolff, Tenderich, and others have recommended osteoplastic operations with varied results. All methods failing, strong elastic bands may be made to duplicate the action of the extensors and must be permanently worn. Ankylosis following resection of the patella is better for those who cannot afford expensive apparatus —a last resort it is true, but to be preferred to a limb incapable of extension.

Suture of the ruptured peripatellar and parapatellar aponeuroses is of the utmost importance. Whether it be of the quadriceps tendon or of the ligamentum patellæ, it is an injury the repair of which is equal in importance to that of fracture of the patella itself. Immediately following fracture of the patella the lateral expansion of the rectus, vasti, and sartorius, together with the fibers of the fascia lata proceed at once on the vicarious function of extension.

Following are statistics of thirty cases treated in the Massachusetts General Hospital, in which final results were noted:

Unsutured, 6 cases, as follows:

Result.	Cases.	Per cent.
Perfect	3	50
Fair	1	16.5
Poor	2	33.5
Serviceable knees	..	66.5

Sutured, 24 cases, as follows:

Result.	Cases.	Per cent.
Perfect	17	65.5
Fair	5	19.0
Poor	4	15.5
Serviceable knees	..	84.5

CONCLUSIONS

As between the operative and non-operative methods, in the absence of a competent surgeon with all antiseptic precautions, the non-operative, conservative, treatment should be the rule. On the other hand operative procedure *obtains a better functional result and obtains it* much more quickly than the non-operative procedure, and may be confidently relied on in the hands of those who have formed the habit of taking all the necessary precautions.

With operation, the chances for bony union are far greater; the torn aponeuroses can be repaired and there is far less danger of refracture. The most satisfactory results are obtained by the oval incision, convexity downward, and suture of the patella; by this method joint diffusion is promptly relieved by irrigation or dry sponging; the fibroperiosteal interposition is entirely removed; apposition of the fragments is exact; tilting is corrected; massage and passive motion can be begun earlier, the whole process of repair, recuperation and convalescence is hastened. It admits of prompt and complete removal of all detached bony fragments; all articular effusions, and all extravasated blood, intra-articular or extra-articular, liquid or clotted.

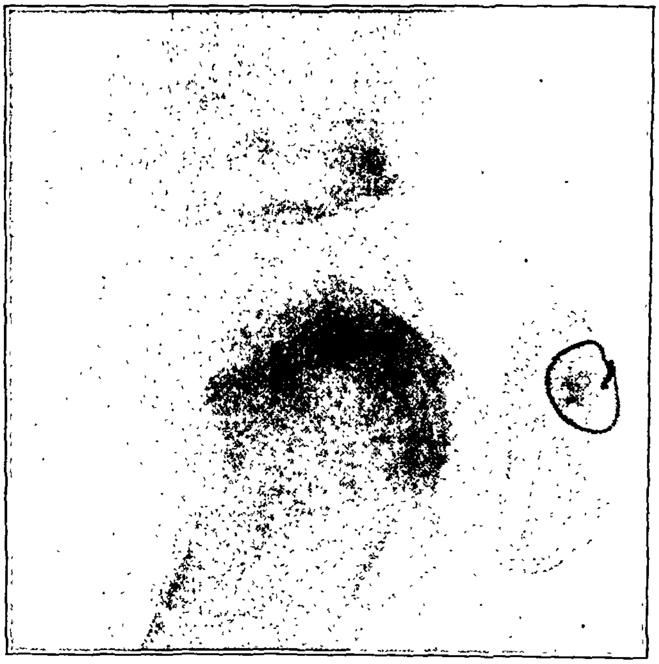

Fig. 3.—Same case as shown in Figure 2. Joint radiographed seven months after operation by Dr. T. A. Groover; illustrating bony union; function almost perfect, flexion 45°, extension 180°, respectively. No atrophy of the quadriceps; patient goes up and down stairs without difficulty.

The subcutaneous operation is to-day obsolete. Its latest chief advocates, König and Kocher, are now most enthusiastic in their adoption of the open method.

The circumferential loop has few followers, as has that method by which the bony fragments are simply apposed and the suturing confined to the peripatellar tissues.

The dangers of the open method, done under proper precautions and by competent men, are practically *nil*. A point deserving of special emphasis is the after-care of the patient—an absolute requisite to success.

In interposition, operation is imperative.

Wire should never be carried deep enough to penetrate the joint as it will irritate the cartilage and produce an arthritis.

Impaired function results in union from faulty position.

The combination of the interrupted and reinforced continuous chromic catgut suture is the making of assurance doubly sure.

Absolutely accurate coaptation and repair of the accessory extensor aponeuroses are vitally essential—in some cases even *more important than coaptation and repair of the bone itself.* Eminent authorities to the contrary notwithstanding, bony union of the transverse fracture—the one most difficult of functional repair—can certainly be accomplished if the carefully sutured bone is reinforced by an equally carefully sutured aponeurosis.

If exposure is decided on at all then ample exposure of the field of injury under aseptic precautions is always justifiable.

Other things being equal, the oval incision, convexity downward, admits of the best drainage, should necessity for drainage arise; while at the same time it retains anatomically the best arterial and nerve-supply.

The most progressive European and American surgeons are in one accord that by far the best results are obtained by the open method and suture.

The suture material, if non-absorbable, should be the smallest consistent with the requirements, and the possibilities of pressure-necrosis should be reduced to the minimum by complete extension of the limb held in the oblique position, which insures the great desideratum of every method of treatment—complete inactivity of the quadriceps extensor.

A WATER-CURTAIN FOR COOLING ROOMS

PRACTICAL FOR CROWDED WORKROOMS, FACTORIES, HOSPITAL WARDS, TENEMENT HOUSES, AND FOR COLLECTING DUST

WILLIAM J. MANNING, M.D.
Medical and Sanitary Officer, Government Printing Office
WASHINGTON, D. C.

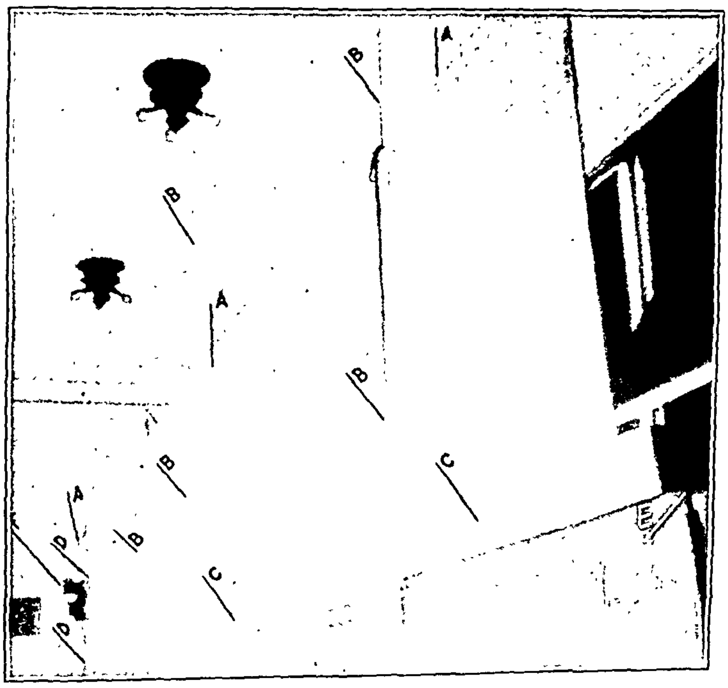
It is intended to show, by the illustration here presented, a simple, cheap, but effective, method for reducing the temperature and collecting dust in sick-rooms, crowded factory workshops, tenement houses, etc., during the summer in large cities, which may also be adapted to residences in tropical countries.

Various methods have been in vogue for cooling purposes in large buildings by the use of ammonia and brine coils, but they are very expensive to instal, often costing thousands of dollars, and are heavy and cumbersome. There are other possible objections to be urged against the refrigerator method. For instance, all windows in the rooms must be kept closed, and for this reason, in the subtraction of moisture from the atmosphere, there is a possibility that with the condensation of the aqueous vapor in the form of frost on the coils other necessary normal constituents of the atmosphere are extracted and withdrawn at the same time. Too great a chill may be produced in contrast to the hot weather and high temperature elsewhere existing outside the building in which the ammonia system has been installed, with, of course, disastrous results, so far as health is concerned, to employees or occupants of the building on emerging into the heated atmosphere from the cooler air, or the rapid cooling of a perspiring body on sudden, incautious entrance into a chilled room.

The simple, safe, old-fashioned method of shaking out wet towels in the sickroom and hanging them over the head of the bed to cool the temperature, as practiced for many years in country districts, gave me the first idea on which I have attempted to elaborate somewhat and to utilize and adapt it in a large way to modern living and working conditions in large cities during the hot season.

The system is one of absorption of moisture by the atmosphere and varies, of course, with the humidity present in the air as to the amount of water taken up by evaporation. The tests were made in the emergency room at the Government Printing Office, Washington, D. C., which is approximately 45 by 15 feet in size. I have been enabled to reduce the temperature from day to day, the reduction varying from 6 to 11 degrees F., through the amount of humidity present and temperature of water during the past summer. When a temperature of 96 F. or 98 F. exists, in the shade, the reduction mentioned is very much to be appreciated.

The water-curtain is made up and consists of a tin speaking-tube (*aa*), the sections of which have been soldered together and perforated with one-eighth-inch holes at a space of one inch, to make the required length of 40 feet for the experiment. The speaking-tubes, of course, by adding sections, can be made any required length up to even 300 or 400 feet, if necessary. From this hangs suspended a strip of cotton twill some 3 feet in width and 40 feet in length. In the top of the curtain a large hem has been taken, through which the perforated tin speaking-tube is run, somewhat like a window-blind stick in a window-curtain. The tube is connected at one end with an inlet (*dd*), consisting of a piece of rubber tubing connected, in turn, with a water-faucet on the wall, the other end of the described tin tube being blind. Perforations in tin tube can be made with a nail. The rubber tubes at *dd* and *ee* are connected with trough and tin speaking tube within them, respectively, by means of tin "thimbles" or small tubes surrounding the orifices made for outlet and inlet.



Water-curtain for reducing temperature in sick-rooms, factories, etc.

A box suspended against the wall over the curtain and lined with zinc to prevent leakage may be utilized, if there is no running water in the room, and may, in addition, be filled with ice, which will serve to give a degree or more lower temperature than the city water-supply. A wash-boiler with faucet on the end will answer nicely for this purpose.

At the bottom of the cotton fabric is a tin trough (*cc*), in the center of which, at the bottom, are soldered eye screws, which, in turn, connect with an iron rod pushed through a hem taken in the lower part of the curtain or fabric. This enables the curtain to be drawn taut and hang directly down into the trough (*cc*) and prevents dripping from the sheet above to the floor.

The water-curtain is suspended from the ceiling by chains or rods (a clothesline answers very nicely), which, affixed to the ceiling, continue downward to the tube (*aa*) and thence down to the edge of the trough (*cc*), thus giving the necessary balance and stability to the whole scheme, as shown in *bb*.

The trough is set slightly at an incline to give the necessary runway for drainage purposes through the pipe marked *ee*, which may be allowed to run waste or be conducted back by a siphon effect to *dd* and there mix with the cold fresh water and be utilized over again.

At the point marked *f* an electric fan is placed directly at one end of the curtain, which serves to hasten the rapid evaporation of the water from the curtain by a continuous series of serpentine or wave-like movements imparted to the sheet its entire length; but in cases in which the fan cannot be employed, the same effect (a continuous lowering of the temperature) is obtained, but almost twice the length of time is required to reduce the temperature in the room to the same degree.

One of the advantages of this method is the fact that it will continue its work without further interference or manipulation during a hot night, in a noiseless manner, and requires no more attention than the simple turning off or on of the spigot or faucet on the wall connected with the rubber tube (*d*).

The curtain, by means of the water escaping by capillary attraction downward, is kept in a state of saturation to an excess, and it is, therefore, constantly soaked and dripping with water.

Formalin or similar agents may be conducted into the inlet (*d*) from a container placed somewhat higher up on the wall than the curtain, in such proportion as to mix with the water at a given percentage, and, in addition to the reduction of temperature, accomplish germicidal results.

The well-known natural law of the attraction of smaller bodies toward a larger mass is taken advantage of in the collection of dust in the air, which is held in place by the cohesive wet surface of the curtain. The fabric may be removed for washing purposes in a few moments' time after it has been covered with dust in the manner described, and a clean, duplicate fabric substituted.

No method, feature, or appliance has been patented in connection with curtain, and it may be freely utilized by individuals or hospitals for their respective needs.

It will be noticed that the whole system is very inexpensive, the tin speaking-tube costing but two cents a foot, the necessary trough five cents a square foot (constructed by any tinner), the cotton twill six cents a yard, and the rubber tubing eight cents a foot.

This opportunity is taken to thank my assistant, Dr. D. P. Bush, for interest shown and for valuable services rendered during the construction of curtain and while conducting the experiment.

1246 Eleventh Street.

THE TREATMENT OF GONORRHEA WITH REFERENCE TO THE QUESTION OF STERILITY*

B. C. CORBUS, M.D.

Instructor in Genito-Urinary Diseases, College of Physicians and Surgeons, Medical Department of the University of Illinois.

CHICAGO

In 1901 there were approximately 162,372 patients suffering from venereal disease in New York.[1] Although we have never had any investigation to compile statistics here in Chicago, I have no doubt that the number of venereal patients is equally great. In New York 15,969 cases of gonorrhea were reported, of which 1,941 were in women. The proportion of men to women is about 15 to 1; of these one-third were in women who were infected after their marriage.

While it does not seem possible to limit promiscuous sexual intercourse, it does lie within the bounds of possibility to limit the transmission of the disease by "bacillus-carriers" through a careful and systematic management of cases from the microscopic standpoint of the discharge.

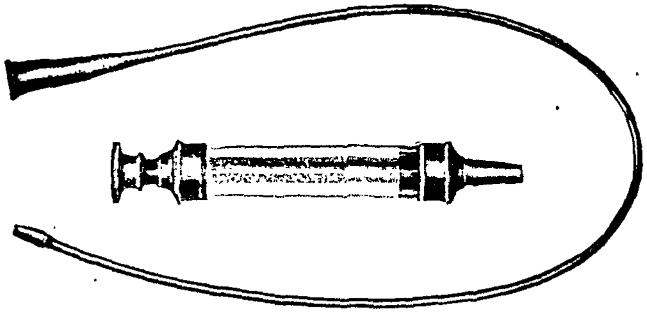


Fig. 1.—Guyon capillary syringe.

The gonococcus has its own peculiar characteristics which enable it to be differentiated from other organisms. It grows best on ascitic fluid agar and its macroscopic appearance is fairly characteristic. The colonies when grown twenty-four hours at 37 C., appear circular, resembling dewdrops, are grayish blue and transparent, slightly iridescent, and about 1 mm. in diameter. In gonorrheal pus the prevailing form of the diplococcus is the "coffee bean" or "roll" shape.

The gonococcus is particularly characterized by being found within the protoplasm of the pus cell and never in the nucleus. Although appearing in thick smears to be within the nucleus, the bacilli are in reality on top. This position is less frequent in the early stages, but it is the rule in the stage of excessive purulent inflammation. In the later stages there are fewer leucocytes and the cocci are found in the epithelial cells or often free in groups. In acute and chronic cases the cocci are often extracellular.

In recent gonorrheal infections of the genital mucosa, the microscopic demonstration of the gonococcus is not difficult. The many methods for staining the gonococcus have no advantage over Loeffler's methylene blue, because they are of no value in differentiating it from other organisms, as they all take the stain. By the addition of a little ammonia to Loeffler's methylene blue, the leucocytes, epithelial cells and cocci are all intensified and as a consequence the picture is made more vivid.

The only staining method which possesses any certain value for differential diagnosis of the gonococcus, however, is the Gram method. If the smears have been made evenly thin and have been properly stained, the *gonococcus in gonorrheal pus and in cultures is always completely and rapidly decolorized. In the same manner* they can be differentiated particularly from a number of cocci, including some diplococci, which occur under the normal[2] conditions in the male and female genital tract.

---

* Portion of a paper read before the Chicago Medical Society, March 2, 1910.

[1] Med. News, 1901, lxxix, 962.

Nevertheless, *microscopic examination* in gonorrhea, especially in chronic cases in which a few suspicious cocci are found, is not always dependable. In such cases it may be necessary to culture the organism.

The most frequent cause of sterility in the male is *gonorrheal epididymitis.*

If *the epididymes are attacked by inflammation,* complete obliteration of the ducts not uncommonly results. It is immaterial from what cause the inflammation develops, the results are the same; all depends on the *degree and extent of the inflammation.* An injury to the epididymis, syphilis, tuberculosis, carcinoma and sarcoma may produce an occlusion, but these conditions are indeed rare in comparison to gonorrheal epididymitis, which, according to statistics,[3] occurs in 7 to 14 per cent. of all cases.

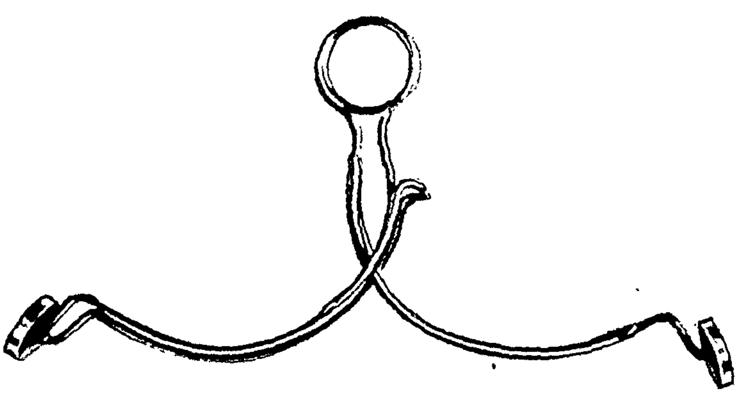

Fig. 2.—Urethral clamp.

ANTERIOR URETHRITIS

With the passing of the irrigation treatment for acute specific anterior urethritis, the *attending posterior urethritis* with its complications is fast diminishing. During the past three years I have treated about 200 cases of urethritis in private practice and the resulting involvement of the epididymes was less than 0.5 per cent. The management of the cases was as follows:

INSTRUMENTS AND MATERIALS

I. INSTRUMENTS

1. *Capillary Guyon syringe.*
2. Large glass syringe with blunt nozzle holding about 10 c.c.
3. Set of sounds or flexible bougies.
4. A suitable clamp for holding the meatus.

II. MATERIALS

Two per cent. stock bottle *albargin in dark-colored* bottle.

Four dark one-ounce bottles containing respectively 0.25 per cent., 0.5 per cent., 0.75 per cent., and 1 per cent. nitrate of silver.

Having satisfied myself that I have a *specific urethritis to deal with* I proceed as follows:

The patient is instructed to urinate in two glasses (this test is of no value unless the patient has held his urine for at least four hours). In a large majority of acute cases, if seen before the fifth day, the infection has not yet become posterior, as will be seen by the urine glasses, the first will be cloudy with specks, the second clear, showing that the case is one of a simple anterior urethritis.

If the cases are handled according to the following method, there will be no further trouble:

The patient is placed on his back (or if one prefers *to have him stand there is no objection, unless there is an extreme grade of inflammation*). Ten c.c. of a 2 per cent. solution of albargin heated to 104 F. are gently injected into the anterior urethra by means of the glass syringe. Pressure is made at the juncture of the anterior and posterior urethræ to keep any fluid from passing backward. This is especially important in cases of relaxed external sphincters. *This solution is held in the* anterior urethra three to four minutes, by means of a small clamp that gently holds the meatus together. After allowing the injection to flow gently out, a loose dressing is placed over the penis to allow for good drainage. *On no consideration is the patient allowed* to crowd cotton between the folds of the prepuce to check the discharge.

The patient is next given a hand injection, either 0.25 per cent. protargol, or 0.1 per cent. albargin, and instructed to use it four or five times a day, care always *being taken not to use any force and to make pressure at* the posterior end of the anterior urethra during the injection. For the high-grade local inflammation that is always present and which is exaggerated by the warm injection, the patient is instructed to immerse the penis *in a glass of hot water for fifteen minutes, two to four* times on the first day, always using great care to keep the water as hot as possible the whole time. This procedure will rapidly take out the inflammation and permit the continuance of the treatment.

On the second day the discharge is examined and *carefully noted, to see if the gonococcus is still present.* Occasionally, when the duration of the urethritis is under thirteen hours, one injection is sufficient to drive the gonococci out of the urethra. Whether they are present on the second day or not, however, I continue the treatment for four days; 2 per cent. albargin hot in the anterior urethra at the office and the hot immersions and injection at home. If for any reason on the second or third day there is the slightest suspicion of a hemorrhage, cold 2 per cent. albargin solution *is substituted* for the hot solution, and the patient is told *to reduce* his hand injections to one or two *times a day,* but to continue the hot immersions as previously.

On the third day the discharge is again examined and a careful search is made for the gonococcus. If cocci are absent, the same *treatment is continued* for another day (four days in succession); *on the other hand,* if they are still present, the treatment is continued until the organism is absent and has remained so for four successive days, great care being always taken to discontinue the 2 per cent. albargin entirely *if the hemorrhage* is in the *least persistent.* If the hemorrhage is at all severe, all *local* treatment within the urethra is suspended, but the suspension in hot water is continued.

We now assume one of the following: Either (1) that the gonococcus has disappeared entirely from the *urethra, or (2)* that it has invaded the deeper layers of the mucosa or glandular tissue and does not appear in the discharge.

Now, provided the organism has been absent for four successive days and the local *inflammation* has subsided, a 1 per cent. nitrate of silver solution is gently passed into the anterior urethra. With this solution in place the urethra is gently massaged, the same precaution always being used about constricting *the anterior* urethra at its junction with the posterior urethra. The

---

[2] Kutscher Berl. klin. Wchnschr., 1909, xlvi, 2059.

[3] Finger: Blennorrhœ, Leipsic and Vienna, 1905, p. 309.

1 per cent. nitrate of silver acts as a harrow; it causes a large amount of desquamation and in so doing may dislodge any organisms that have invaded the deeper layers of the mucosa.

The patient is instructed to continue his hand injection for two days, at which time he presents himself for another microscopic examination. If on the second day after the 1 per cent. of silver injection, the gonococcus again makes its appearance, it is necessary to start from the beginning, treating this acute exacerbation as an acute attack, and to proceed all over again. On the other hand, if no organisms are present, a well-lubricated bougie (one that just fits into the meatus snugly) is passed the length of the anterior urethra, care being taken not to produce any traumatism. With this in place the urethra is gently massaged. This is followed by a 2 per cent. albargin injection cold.

The patient is then instructed to use his hand injection for several days longer, and at the end of which time, if there are no organisms present, he is given a rest for five days, being instructed to return at the end of the fifth day. If the microscopic examination of the discharge shows no gonococci at this time the patient is instructed to dring some beer; if this does not cause a return of the discharge in thirty-six to forty-eight hours, he can be considered well.

In all cases of simple anterior urethritis in which there are no complications, the patient is instructed to discontinue the use of alcoholic drinks for one month after his test drink, as they tend to aggravate a "post-gonorrheal catarrh." In a large percentage of cases when you have removed the cause (the gonococcus) all that is necessary is to keep the functions of the body active and the discharge will cease.

Astringents are to be emphatically condemned, as a discharge that persists in spite of careful dietetic and hygienic care is sure to contain cocci and suppression of the discharge only tends to lock the gonococci tighter within the urethral mucosa.

In a few exceptional cases, especially after a prolonged course of treatment, a catarrhal condition of Littré's glands which calls for astringent treatment may occur.

POSTERIOR URETHRITIS

Few patients with simple anterior urethritis, if seen early and treated in the above manner, acquire posterior involvement.

When the two-glass test shows an involvement of the posterior urethra, I proceed as follows (always having the patient empty his bladder before treatment): Depending on the severity of the symptoms, 0.25 to 0.75 per cent. nitrate of silver are passed into the posterior urethra, by means of the Guyon capillary syringe. If there is the slightest irritability and tenesmus, only the weakest solution is used; following this the anterior urethra is injected with hot 2 per cent. albargin, the same precaution being used not to let it pass posteriorly. The anterior treatment is continued daily with the same limitations as for acute anterior urethritis, but the posterior treatment is not resumed until the third day. Should the irritability and tenesmus increase in severity, all treatment, both anterior and posterior, are discontinued, and the patient is given a saline laxative, hot sitz baths and rectal suppositories containing the following:

℞.	gm.	
Extracti belladonnæ Extracti opii, āā	0|25	gr. iv
		or
Ichthyolis Iodoformi, āā	2|50	gr. xlv
Butyræ cocæ q. s.		

M. Fiant suppos. rect. No. X.
Sig.: Insert one every six hours.

On the third day, provided the acute posterior symptoms have all subsided, the prostate is gently massaged and 0.25 to 0.5 per cent. of nitrate of silver is given by the Guyon catheter, followed by the anterior treatment. No matter how slight the posterior infection may be, there is always a corresponding involvement of the prostate, and the posterior infection will not clear up unless the prostate receives its corresponding attention. In acute cases it is seldom necessary to use stronger solutions than 0.75 per cent. nitrate of silver posteriorly. When the urine clears in the second glass and the prostate shows no pus microscopically, a bougie is passed all the length of the urethra, but the 1 per cent. nitrate of silver is omitted in the posterior urethra. If this does not produce a recurrence, the beer test is applied. If the gonococci are still absent and the urine glasses clear, the patient can be considered well. In the event that the gonococci appear again, however, it is necessary to start as from the beginning.

In all cases of acute posterior urethritis it is advisable to put a good snug-fitting suspensory on the patient—not the ordinary suspensory that simply holds the scrotum together, but one that raises the testicles well up toward the pubes.

I have intentionally omitted all reference to the internal treatment and the management of complications, as space does not permit their discussion here.

For the management of acute infections of the epididymis, you are referred to the excellent works by Belfield, Hagner and others.

CONCLUSIONS

1. Specific urethritis is increasing in frequency.
2. More attention should be paid to its detailed diagnosis and treatment.
3. Methods of treatment should aim at the easiest and simplest way of combating the disease.
4. With this in view the spread of specific urethritis will be greatly lessened.

100 State Street.

A STUDY IN RENAL SENESCENCE*

JOSEPH WALSH, M.D.
PHILADELPHIA

In a study of the kidneys four years ago I thought I noticed a fact which I had never heard mentioned, namely, that as age advanced there was a thickening of the interstitial tissue at the apex or papillary end of the pyramids and that this thickening was reasonably uniform. Further study on one hundred and fifty kidneys from individuals of all ages dying from many different diseases (though the majority died from tuberculosis of the lungs) added confirmation. I then showed a number of unselected specimens, the identification of which was withheld, to Dr. McFarland, who was so successful in determining the ages of the patients by the criterion mentioned that I have thought it worth while to prepare the following notes for publication.

---

* From the Laboratory of the Henry Phipps Institute; read before the Philadelphia Pathological Society, Feb. 24, 1910.

The condition is practically one for demonstration rather than for description, yet the specimens shown at the time of the reading of the paper might be described as follows: The specimen from the child one month old showed through a ⅔ lens the tubules at the apex of the pyramids practically in juxtaposition with so little interstitial tissue between them that it was practically invisible; in the 9-year old specimen there were one or two fine lines of interstitial tissue between the tubules; in the 27-year-old specimen three or four lines; in the 35-year-old specimen five or six; in the 69-year-old specimen eight to ten lines and in the 99-year-old specimen ten to twenty lines.

Moreover, the study revealed that this thickening of the interstitial tissue was not dependent on the accompanying pathologic condition of the kidney, but occurred apparently only as a result of age. All kinds of pathologic conditions were found in the one hundred and fifty kidneys studied, namely, cloudy swelling, acute parenchymatous nephritis, chronic parenchymatous nephritis, focal interstitial nephritis, the various kinds of general interstitial nephritis, amyloid degeneration, pyelonephritis, etc. It was found that pyelonephritis and hydronephrosis injured the pyramids and increased the interstitial tissue in them to such an extent as definitely to obscure the comparatively slight increase due to age; in these cases, therefore, the age could not be told from the appearance.

In addition it was found that a general or a marked focal interstitial condition which is commonly only studied and described from the appearances in the cortex affected also the pyramids and hence increased the interstitial condition at the apex of the pyramids so that the thickening at this point did not correspond exactly with the age. Comparison of many such kidneys, however, showed that it was not difficult to learn from the condition in the cortex how much of the thickening at the apex of the pyramids was to be attributed to the pathologic condition and how much to age. In other words though interstitial nephritis modifies the amount of interstitial thickening at the apex of the pyramids, this modification can be recognized and taken into account. In regard to the question which naturally arises as to how reliable is the differentiation of age from this thickening of the interstitial tissue, I would say that it is almost as reliable as the appearance of the face; though we can generally give a pretty good idea of the age of an individual by looking at him we are sometimes mistaken in middle life to the extent of ten or even fifteen years and in old age rarely even to the extent of twenty years.

In deciding the age of the individual from the thickening of the interstitial tissue at the apex of the pyramids the following precautions should be taken: First, the apex of the pyramid should be in view. Sometimes a cross-section of the kidney is made in such a way that we see a long stretch of pyramid but instead of one we are looking at two pyramids end to end; in other words, a specimen may be cut across two pyramids in such a way that the apical portion of one pyramid will run into the apical portion of the other so as to make the end of the specimen actually near the second cortex though the second cortex is not in view. Second, edema must be differentiated from thickening of the interstitial tissue. Third, the amount of interstitial tissue should be estimated, not from a single location, but from several fields of a ⅔ lens. Fourth, interstitial nephritis increases the amount of interstitial tissue at the apex of the pyramid and must be accounted for. Fifth, pyelonephritis and hydronephrosis obscure completely the thickening due to age.

SUMMARY

1. There is a gradual increase in the amount of interstitial tissue at the apex of the renal pyramids so uniform with advancing age that the age of the individual is evident from the amount of interstitial tissue found.

2. This relation of the amount of interstitial tissue to the age is lost in cases of pyelonephritis and hydronephrosis; and modified by interstitial nephritis, though this modification can be accounted for, so that the age remains evident.

732 Pine Street.

THE UNCINARIA AMERICANA IN GEORGIA

C. A. WELLS
ATHENS, GA.

Since the investigation of uncinariasis in the South by Dr. Stiles in 1902, a number of examinations have been made for this disease by the Georgia State Board of Health and individual investigators in Georgia. The information so obtained has established with fair degree of certainty the geographical distribution of uncinariasis in this state, but has furnished little positive knowledge of the extent to which the disease prevails. An investigation was begun in this laboratory a little more than a year ago which has led to approximately accurate conclusions on this and certain other phases of the hookworm question.

METHOD OF INVESTIGATION

For the purpose of this investigation the state was considered in two divisions, the northern and southern, the former representing that portion of the state lying north of and including the foothills, and the latter the remainder of the state. From these divisions counties eleven in all—were taken typical of different local areas. From the counties thus chosen groups were selected representative of that portion of the white population subject to hookworm, and then a complete microscopic examination was made of each whole group. The results so obtained are given in Table 1.

The groups referred to above are schools, the examination of which I was enabled to make through the kind cooperation of the principals in charge. In the northern division, Group 1 is a rural school in the mountainous section, and likewise Group 2 which, however, is situated farther west. Both are situated south of and adjoining the Blue Ridge. In these sections a heavy gravelly soil exists with occasional loamy and ferruginous areas. The winters, for this latitude, are rather severe. There is much rainfall during the summer seasons. Group 3 is a school situated in a small town in north central Georgia. Here is found in the main, a light sandy soil locally known as "gray land." Group 4 is a school in a town of about 4,000 inhabitants which has had for the past few years a partial system of sewerage and pavement. The town is situated in middle Georgia just north of the foothills. Group 5 is a rural school located in another section of middle Georgia. Here a light gravelly and sandy soil predominates. In the southern division, Group 1 is a rural school and Group 2 a school in a small town. Both are situated in counties adjoining the state of Florida. Group 3 is a school in a small town near the central part of the southern division. A sandy soil prevails in all three of these localities and the rainfall during the summer seasons is less than that of the mountainous districts of the northern division for the same season. The sanitary conditions prevailing in the different sections of the state represented by these groups, except Group 3 in the northern division, are approximately the same. In the small towns some sort of a surface closet system exists, while the country schools visited were not found to have so much as this to their credit.

In Table 1 the groups already discussed are arranged in order, 1, 2, 3, etc., and each group is subdivided into two classes, A and B. Class A includes examination of persons from 6 to 16 years of age, and Class B of persons from 17 to 26 years of age. The signs + and — signify positive and negative results of examinations for eggs of the uncinaria.

PERCENTAGE OF POPULATION INFECTED

From the data in Table 1 may be calculated the approximate percentage of hookworm infection in this state. The white population of the northern division exclusive of that of Columbus, Macon, Augusta, Athens and Atlanta as estimated from the United States census report is as shown in Table 2 and the white population of the southern division exclusive of that of Savannah is given under Table 3.

TABLE 1.—HOOKWORM INFECTION IN GROUPS INSPECTED

Group	Class A, Age 6-16 inclusive									Class B, Age 17-26 inclusive								
	Males			Females			M. and F.			Males			Females			M. and F.

SOUTHERN DIVISION																		
1	8	0	—	4	0	—	12	0	—	24	18	57	8	9	47	32	27	54
2	14	8	64	22	11	67	36	19	65	7	2	78	2	0	—	9	2	82
3	7	4	63	11	5	64	18	9	67	4	0	—	9	2	50	6	2	75
Total	29	12	71	37	16	70	66	28	70	35	20	64	12	11	52	47	31	59

TABLE 2.—WHITE POPULATION OF NORTHERN GEORGIA, EXCLUSIVE OF CHIEF CITIES

Total	876,225
Class A, age 6-16 inclusive	311,264
Class B, age 17-26 inclusive	215,495

TABLE 3.—WHITE POPULATION OF SOUTHERN GEORGIA, EXCLUSIVE OF SAVANNAH

Total	223,268
Class A, age 6-16 inclusive	79,312
Class B, age 17-26 inclusive	54,909

From Table 1, 38 per cent. of Class A and 27 per cent. of Class B in the northern division, and 70 per cent. Class A with 59 per cent. of Class B in the southern division have uncinariasis. This gives a total for the state of 264,378; or exclusive of the six cities named above, approximately 24 per cent. of the total white population in Georgia have hookworm.

AGE PERIOD OF INFECTION

Infection was not found among children 5 years of age and under, and to no great extent among persons over 27 years of age, though it should be stated that a very small number of either of these classes was examined. The relative percentage of infection was found to increase with age up to about 16. It then remained almost constant to the age of 22. From this it decreased until at the age of 27 it became almost negligible.

SYMPTOMATOLOGY AND TREATMENT

For unavoidable reasons in many cases no record was kept of symptoms. From those which were recorded the following conclusions are drawn:

1. In a great many cases, particularly among the young, the symptoms heretofore ascribed to uncinariasis by competent investigators were very pronounced though they were little if at all in evidence in fully one-half of all cases examined.
2. Thymol is a positively effective anthelmintic if its administration is repeated often enough (in some cases it was found necessary to repeat the treatment as many as five times).
3. Patients almost always improve immediately after the worms have been expelled though a great many seem to be unable to recover fully from the effects of the disease.

RELATIVE INFECTION OF MALES AND FEMALES

In Table 1 the percentage infection of males and females is given, from which it appears that the two sexes are about equally subject to hookworm infection.

RELATION OF GROUND-ITCH TO THE DISEASE

This relation is brought out in Table 4, in which is given the calculation of those who have, and also of those who have not had ground-itch, but who were found infected with hookworm.

TABLE 4.—GROUND-ITCH AND HOOKWORM INFECTION

Ground-itch.	Per Cent. Hookworm Infection.
Not since 1902	11
Between 1904 and 1906	62
Since 1906	82
Not at all	8

In this table three things are indicated: (1) that the uncinaria can live longer than eight years, the longest period found being twelve years; (2) that Nature may eliminate the worms from the intestines in less than eight years, the shortest time found being a little more than two years; (3) that ground-itch, though the chief, is not the only mode of infection. In all three of these deductions it is assumed, of course, that the cases reported were true cases of ground-itch and represent hookworm infections, which may or may not be true, for there are certain cases of ground-itch, so-called, caused otherwise than by larvæ of hookworms. In the words of Dr. Stiles, "probably the term 'ground-itch' covers a multitude of sins."

It may be mentioned also that eggs of *Tænia nana* were found in 3 per cent. of all specimens examined.

SUMMARY

1. Uncinariasis is confined mainly to persons between 5 and 27 years of age.

2. The greatest infection occurs between the age of 6 and 16 inclusive.

3. Symptomatic diagnosis is unsatisfactory; thymol is an effective vermifuge in the treatment of hookworm; in some cases full recovery from the effects of the disease seems to be unattainable.

4. Males and females are infected approximately to the same extent.

5. Exclusive of the large towns, about 24 per cent. of the total white population in Georgia have uncinariasis.

6. Ground-itch is the chief but not the only mode of infection.

7. The uncinaria may live in the intestines from two to twelve years.

RECURRENT FURUNCULOSIS IN AN INFANT SHOWING AN UNUSUAL BLOOD PICTURE

MEDWIN LEALE, B.A., M.D.
NEW YORK

Having failed to find any similar case reported in the literature, I believe that the following will probably be of interest.

The case occurred in my private practice and the child first came under my care in September, 1908, and at that time the following history was obtained.

Mother's History.—The family history was excellent, there being no discoverable hereditary taint. The mother, an unusually robust woman in her thirties, with that nervous energy which so often accompanies an active mentality, toward the end of the eighth month of this her second pregnancy, suddenly developed eclampsia, having, according to her accoucheur, previously presented no untoward urinary findings. The labor was hastened by an instrumental delivery, and the mother was delivered of a well-developed though premature boy baby, weighing about six pounds.

Baby's History.—As the mother could not nurse the infant owing to deficient milk supply, the accoucheur secured a wet-nurse. As the nurse's milk did not agree with the child, after trying fresh milk formulas he was placed on a condensed milk modification. On this, I am told, he improved somewhat, but the food did not prove altogether satisfactory and the infant was placed on the first formula of the "Materna,"[1] which constituted his food until I saw him for the first time at three and a half months of age. At this time his weight was eight pounds. The following information was also elicited. When about eight weeks old, the baby had an attack of suppression of urine which was relieved by hot packs over the kidneys, and on Sept. 7, 1908, one month later, I am told, passed no urine for a period of thirty-six hours. The first few drops of urine passed after this contained blood. One week later, the infant had a similar attack. I could not secure any further accurate information in regard to the urinary findings.

Examination.—I saw the baby for the first time Sept. 20, 1908, when he was three and a half months old, and for the previous twenty-four hours had been fretful and restless with a temperature of 102 F. He had had a number of greenish lumpy and watery stools. I made the following physical examination: A poorly developed baby, weighing eight pounds, slightly marasmatic look, poor color, bony and other tissues soft. He does not notice even loud noises. The pupils react to light rather slowly. The baby does not follow even a strong light with his eyes. His sense of taste is normal. There is a slight tendency to snuffles. There is no skin eruption, and no glandular enlargement. The lungs are normal. The heart presents a roughening of the first sound over the pulmonary interspace, but there is no weakening of the second pulmonary sound. There is no dilatation of the right ventricle, and no evidences of cyanosis or of venous stasis. Abdomen is slightly distended, but there is no rigidity. The liver and spleen are impalpable. The superficial and other reflexes are rather sluggish.

Treatment.—The infant, after recovering from this enteric attack, was placed on gradually increasing and appropriate milk dilutions, so that two weeks later he had gained one and a quarter pounds, and showed corresponding improvement in his general condition. One week later, Oct. 19, 1908, a few pustules appeared on the neck and the chin, which were carefully expressed and dressed. The milk formula was gradually increased to fat 2.23 per cent., proteid 1.12 per cent., sugar 6 per cent. He was getting 7 feedings in 24 hours with 4½ ounces at each feeding. The amount at each feeding, the strength of the food, and the number of feedings were changed from time to time to meet the needs of the child, and on Dec. 14, 1908, his weight was 11 pounds 3½ ounces, a net gain in 2½ months of 3 pounds 3½ ounces.

Course of Disease.—On December 19 of the same year, the baby had another attack of furunculosis and on December 21, thinking that he might do better with a wet-nurse, I secured one who had been carefully watched in one of the maternity hospitals of this city, and after a careful personal examination of herself and her six weeks old baby, put him to the breast, with remarkably satisfactory results. With the exception of one or two slight colds in the head, barring the periods of fever and furunculosis, the baby did splendidly, so that between Dec. 22, 1908, and Feb. 22, 1909, he had gained 5 pounds 11 ounces (weight 16 pounds 7 ounces). On June 15, 1909, his first birthday, the baby's weight was 20 pounds 7 ounces, his height 28¾ inches, circumference of head 18⅜ inches, chest 18½ inches. He had 8 teeth, and his bony and other tissues were normal. His vision and hearing were normal.

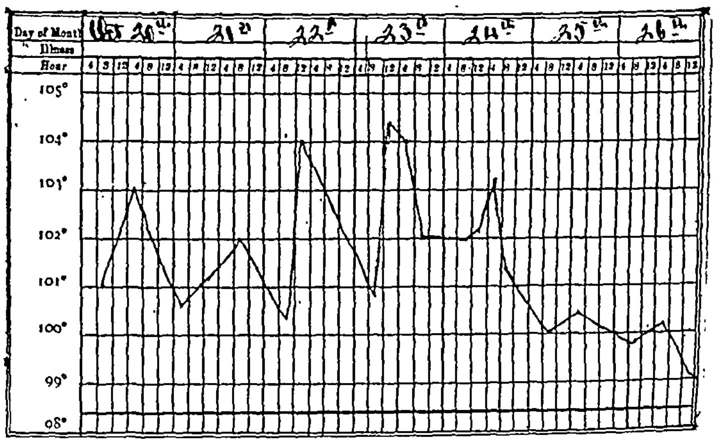

Chart 1.—Temperature curve during October, 1909, attack.

Description of Furunculosis Attacks.—During the period from the onset of the attacks of furunculosis, in October, 1908, the baby had persistent recurring attacks of furuncles accompanied with a rise of temperature, reaching from 102 to 104.6 F. This fever was usually of the irregularly remittent type, and lasted from 3 to 10 days; at one time the fever persisted for over three weeks (Charts 1 and 2). The fever reached its fastigium usually just prior to the ripening of the furuncles, which varied from 2 to 5 in number, and which were accompanied with considerable inflammatory infiltration of the surrounding tissues. Occasionally also an aphthous patch developed on the buccal mucous membrane, and this resulted in considerable necrosis. There was no tenderness of the legs, no abnormal changes at the epiphyses or of the periosteum. There was no sponginess of the gums, in fact, nothing to indicate scorbutus. Instructions were given to start the administration of orange juice after taking the child from the wet nurse, and this and the addition of barley and other cereal gruels to the fresh cow's milk were faithfully carried out. On only two or three occasions was there any marked gastrointestinal disturbance, and at no time was there any evidence of an ulcerative colitis. There was never any vomiting and rarely a diarrhea, the food in reduced quantity as a rule being well digested. During several of the attacks the baby suffered from marked prostration, presumably from sepsis, and the most careful stimulation was required.

---

[1] The Materna is a glass graduate used in the home modification of milk for determining approximate percentages.

Blood Examination.—Repeated examinations of the blood failed to show the plasmodium of malaria, and the condition seemed to be uninfluenced by the administration of quinin bisulphate given in solution. There was at no time a marked anemia, the hemoglobin never being below 55 per cent., and the red blood corpuscles were always up to the minimum normal for that age. There was at no time a distinct leucocytosis, in fact the opposite condition, a leucopenia, was the rule. The unusual feature of the blood picture is the relative leucocyte count which on several examinations over a variable period of time remained very constant, showing an extreme relative lymphocytosis. The following relative leucocyte counts will serve as examples:

Oct. 25, 1909. Differential Count: Small lymphocytes, 65.8 per cent.; large lymphocytes, 32.2 per cent.; polynuclear neutrophils, 1.0 per cent.; eosinophils, 0.8 per cent.; basophils, 0.2 per cent.

Dec. 6, 1909. Differential Count: Small lymphocytes. 61.8 per cent.; large lymphocytes, 34 per cent.; polynuclear neutrophils, 1.0 per cent.; eosinophils, 2.8 per cent.; basophils, 0.4 per cent.

Jan. 12, 1910, the complete blood examination was as follows: Number of red blood corpuscles in 1 cm., 4,800,000; number of leucocytes in 1 cm., 3,000. Differential count: Small lymphocytes, 69.2 per cent.; large lymphocytes, 25.2 per cent.; polymorphonuclear neutrophils, 1.0 per cent.; eosinophils, 3.8 per cent.; basophils, 0.8 per cent. The amount of hemoglobin was 70 per cent. Color index was 0.73. The plasmodium of malaria could not be found on careful search. The red corpuscles were uniform, but somewhat small in size.

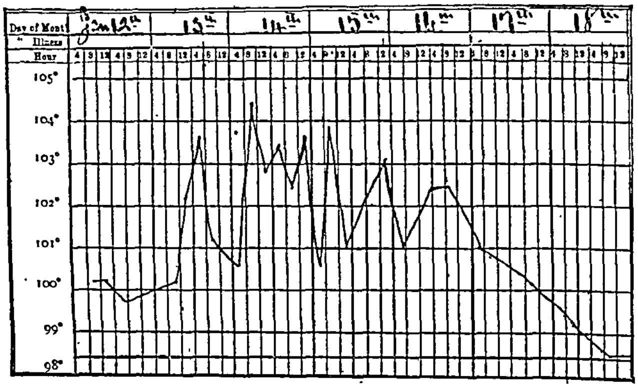

Chart 2.—Temperature curve during January, 1910, attack.

Urine.—The urinary findings on several occasions showed a heavy uric-acid deposit, and during the height of the fever on one or two occasions a faint trace of albumin was detected, but no other abnormal urinary conditions were found.

Micro-organisms.—Cultures from the pustules showed pure *Staphylococcus pyogenes aureus.*

Present Condition.—On Jan. 27, 1910, when the baby was 19½ months old, the following physical examination was made: A well-nourished, active though slightly pale-looking child, very responsive and easily interested, though somewhat nervous. He walks unaided, standing and sitting erect. His head measures 19 inches, chest 18⅞ inches, abdomen 18⅛ inches, and length 30 inches. His weight is 22 pounds, 7 ounces. His legs are straight. The anterior fontanelle is closed. The condition of all the bones is normal. He has 15 teeth, perfectly formed. His back is straight, and muscles are firm. The heart, lungs and abdomen are normal. There is no enlargement of the spleen or of the lymphatic glands, and no evidence of enlargement of thymus. Sensation, throat, eyes and ears normal.

Here, then, is the case of a baby who was born prematurely, who suffered from a marasmatic condition during the first few months of his existence, but who at one year of age and thereafter showed but slight if any departure from the normal in physical and mental development, but who was subject to repeated attacks of furunculosis, with accompanying fever and prostration all out of proportion to the clinical findings, and who also presented the unusual blood picture of an extreme lymphocytosis without other marked blood changes.

It is extremely difficult to account for this great proportion of lymphocytes. Lymphatic leukemia would be thought of, but the absence of a leukocytosis, and the absence of enlargement of the lymphatic glands and of the spleen, with the other clinical findings, would exclude this diagnosis. The periodicity of the fever coming on every few weeks would naturally suggest malaria, but repeated and most painstaking examinations of the blood by myself and several well-known clinical pathologists failed to find the plasmodia, and as has been stated there was no splenic enlargement.

The infant was never markedly anemic; there were no evidences of the "constitutio lymphatica"; at no time were there any symptoms of rachitis or scorbutus; and from the nature of its recurrency the infectious diseases may be excluded. There was nothing either in the history or the clinical findings to suggest specific disease. An enlarged thymus could not be detected.

In all probability, the fever is to be accounted for by the toxemia generated by the *Staphylococcus pyogenes aureus* during the attacks of furunculosis, but this does not satisfactorily account for the peculiar blood findings.

As every attention had been given to the feeding, the general hygiene of the infant, and the local treatment of the suppurative areas, without giving permanent relief from the recurrency of the attacks, an autogenous vaccine is being prepared at the bacteriologic laboratories of the College of Physicians and Surgeons, and careful injections of the vaccine will be made at intervals with the hope of establishing a partial or complete immunity to the staphylococci.

Since submitting this article for publication, during a period of two months, the little patient has had no return of the attacks, and his general health is excellent. The immunizing process was kept up over a period of six weeks, an injection of the vaccine being given at intervals of from five to ten days, in gradually ascending dosage. During this time he has shown no disagreeable symptoms, the vicious cycle of the attacks has been broken, and an immunity has been established. How long this immunity will last time alone will prove.

852 Lexington Avenue.

Therapeutic Disregard of the Laws of Gravity.—R. Blondel in an article recently reviewed in the *Gazette Médicale Belge*, March 17, mentions among other ways in which the attraction of gravitation is disregarded in medical measures, that patients generally put on an elastic stocking like an ordinary stocking, after they have left the bed and the blood has had a chance to settle in the limb. How few physicians, he remarks, think of advising the patient to put on the stocking before arising, and not until after the limb has been held vertically for a time to allow the blood to leave it, the expulsion of the blood being promoted by gentle kneading downward and the stocking being drawn on by another's hands if possible. Abdominal bands should also, he says, be applied while the patient reclines, the individual merely lifting the pelvis from the plane of the bed to permit the band to be passed beneath the body. If corsets were put on also in this way, much would be gained. He also warns that after operations the pelvis should not be lowered too abruptly from the Trendelenburg position.

ANIMAL EXPERIMENTATION IN RELATION TO PRACTICAL MEDICAL KNOWLEDGE OF THE CIRCULATION*

JOSEPH ERLANGER, M.D.
MADISON, WIS.

III. CIRCULATORY SYMPTOM-COMPLEXES AND THEIR TREATMENT

(Concluded from page 1774)

An attempt was made in Part II to make it clear that, whereas the attention of the ancients was attracted to certain symptoms, such as palpitation and syncope, owing to their lack of knowledge of the structure and functions of the heart and blood-vessels, such symptoms were not associated with specific diseases of the circulatory system.

CLINICAL CONCEPTS AND ANIMAL EXPERIMENTATION

It has been shown, furthermore, how, in the seventeenth and eighteenth centuries, when post-mortem observations made possible the building of a firm foundation for anatomy and after Harvey's demonstration of the circulation of the blood, the clinical concepts as we now know them began to appear. This fact in itself sufficed to indicate in a general way the dependence of our modern conceptions on the results of experiment. It might, however, be well to call attention to this dependence in somewhat greater detail.

Why valvular defects, both organic and relative, should alter the action of the circulation, and how, becomes perfectly evident when they are viewed in the light of facts demonstrated by experiment. If the lesion causes a stenosis or insufficiency of any valvular orifice, the knowledge of this fact suffices to account for practically all of the signs and symptoms of the disturbed function. Given, for example, narrowing of the mitral orifice, with a knowledge of the physiology of the circulation, the clinical picture is almost completely understood. The relation of the adventitious to the normal heart-sounds, the enlargement of the left auricle, the engorgement of the pulmonary circulation and its consequences, the hypertrophy of the right auricle and ventricle, the pulsation of the liver and of the veins of the neck, as well as other signs and symptoms, become perfectly clear and are seen to be part and parcel of one and the same thing.

The conception of relative or muscular insufficiency of the valvular orifices rests almost entirely on inferences from results of animal experiments. As long as the Hippocratic idea of the parenchymatous nature of the walls of the heart held sway, the possibility of a variability of the diameters of the cardiac orifices was entirely precluded. When, however, Harvey, Borelli and others[1] recognized that the movements of the heart resembled those of muscles, and after the property of tone in heart muscle had been discovered by Gaskell[2] the way was opened for the clinical conception of valvular insufficiency due to muscular weakness.

The hypertrophied heart, the *cor bovinum,* as a purely anatomic conception, was one of the earliest cardiac lesions to be described. Suggestions as to its causation were not, however, made until it was recognized that the heart, not the blood, did mechanical work and that the amount of work performed by the heart was subject to variation. Practically the only cause of hypertrophy of voluntary muscle is increased work; then why not of heart muscle, too? When, therefore, a hypertrophied heart is met, the physician, in order to discover the cause, looks for the factor that has increased the work of the heart. Physics teaches that work is proportional to the product of the pressure and the surface. "It is, therefore, not a matter of chance that the first to measure the blood-pressure in animals (Hales) was also the first to attempt the estimation of the work of the heart."[3] Since the surface area of the heart and the pressure against which it contracts both are subject to variation, it is to these factors that the clinician looks in order to account for hypertrophies of the heart. In this way many of the etiologic factors of cardiac hypertrophy have been brought to light. It has served to explain the hypertrophies associated with valvular lesions. It has likewise served to explain the cardiac hypertrophy of pulmonary emphysema, of arteriosclerosis, of chronic asphyxia (Hensen[4]), in which condition the blood-pressure is elevated, of many cases of nephritis in all of which the arterial blood-pressure is high, of plethora (which probably increases the work of the heart, not by increasing the blood-pressure, but rather by increasing the amount of blood in, and consequently the area of, the heart (Tigerstedt[5]), and of adhesive pericarditis.

The fact that the dilated heart has great difficulty in maintaining the circulation is likewise seen clearly when viewed from the standpoint of mechanical work.

The concept of the weak heart rests on the fact that the heart acts as a force-pump. The signs of failure of the pump, the fall of arterial pressure, engorgement of the veins, etc., are explained by the discovery of Harvey and its elaborations.

Paroxysmal tachycardia is probably merely a symptom of a number of affections of the heart. Through modern clinical methods, which are largely the outcome of work on animals, the behavior of the heart during the paroxysms has been discerned and at least one cause of the symptoms has been determined, namely, pressure on the vagi (see below.)[6]

The investigation of bradycardia has met with better success. There can be recognized by the application to the human being of methods employed in the laboratory: (1) complete bradycardia, that is, slowing of the whole heart and (2) partial bradycardia, by which is understood the slowing of certain parts of the heart below the mouths of the great veins. Clinical experience, in the light of facts accumulated in the laboratory, has led to the recognition of at least two causes of complete bradycardia, namely (a) direct or reflex stimulation of the cardio-inhibitory mechanisms by asphyxia, by arterial hypertension as in acute nephritis,[7] by increased intracranial tension,[8] by irritation of the gastro-intestinal canal and peritoneum;[9] and (b) slowing of the rate of discharge of the mechanism that sets the pace of the heart (Stannius, Gaskell)[10] through the depressing action of poisons or arteriosclerosis. Clinically these two types may be distinguished in man (Dehio) by means of a laboratory test which depends on the fact that atropin paralyzes the vagus terminals in the heart.

9. Based on experiments by Goltz: Virchows Arch. f. path. Anat., 1863, xxvi, 10.
10. Gaskell: Experiments described in Phil. Tr., London, 1882, p 993.

Animal experiments (Stannius, Gaskell,[11] and others) have brought to light, and have determined the causes of, the type of bradycardia termed incomplete; and the applicability of this work to the condition (Stokes-Adams disease, etc.) as seen in man has been demonstrate by animal experimenters (Chauveau, His, Erlanger,[12] etc.) employing in the clinic the methods of the laboratory. These, by showing that the most common form of incomplete bradycardia is atrioventricular heart-block, have very recently served to elucidate a clinical picture that has puzzled the medical world ever since it was first described some seventy years ago.

It is almost too early to predict the outcome of the efforts now being made toward a better understanding of the cardiac arrhythmias. That they have opened a new era in the detection and analysis of cardiac disease is perhaps all that can now be affirmed. However that may be, the result up to date has been that through the clinical application by Wenckebach,[13] MacKenzie,[14] Hering and others, of facts revealed in the laboratory by Marey, Gaskell, Engelmann, Hering and others, heart irregularities such as extrasystoles, allorrhythmia, the absolutely irregular pulse, etc., which heretofore have had no significance whatever, now stand for specific disturbances of the cardiac motor mechanism.

Reference has already been made to the part animal experimentation and experimenters have played in calling the attention of clinicians to the mechanism that comes into play when, as in arteriosclerosis, the arteries become inelastic.[15]

Arterial aneurism was recognized in man by the animal experimenter, Galen, and attempts at treatment were made by him. Just what part animal experimentation played in the development of this phase of the subject cannot be determined. However that may be, many signs and symptoms of great significance in the diagnosis of aneurism have since come to the clinician through, or have been rendered clear by, experiments on animals or animal experimenters. Harvey, for example, first called attention to the changes of the pulse. Pressure changes in the arteries have also been detected and for their recognition Williamson finds that "the sphygmomanometer is much more sensitive than the finger."[16] The pupillary effects of aortic aneurism are explained by experiments on the cervical sympathetic, some of which were performed as early as 1727,[17] and by local changes in blood-pressure.[18]

The localization of arterial and of most venous emboli from dislodged thrombi is explained perfectly by the circulation. And experimentation has served to throw light on many of the problems connected with the subject of thrombosis. These experiments have demonstrated that slowing of the blood-system *per se* does not cause clotting, although it has been shown by deduction from experiments on animals when the necessary factors are present, decreased velocity plays an important part in thrombosis.[19]

ANIMAL EXPERIMENTATION AND THE TREATMENT OF CARDIOVASCULAR DISEASE

To animal experimentation must also be attributed many of the most valuable suggestions as to the treatment of cardiovascular disease. It will, however, be possible to call attention to only a few instances of this most practical phase of the subject.

It is self-evident that with the discovery of the circulation, and only after the elucidation of the part played by the several mechanisms concerned in its maintenance, the rational treatment of the diseases of the circulation by mechanical means became possible.

Then it became possible to appreciate why patients suffering from "delinquium animi or swooning" should be placed in the recumbent position rather than "in an easy erect posture" as suggested by Paul of Ægina and why other practices, some of which are mentioned in Part II, were to be eliminated as irrational.

Bleeding, than which no form of treatment has passed through as many vicissitudes, illustrates how fruitless may be the results of uncontrolled speculation in medicine, the vacillation "in the practice of this therapeutic measure depending intimately on the prevailing views on blood and juices, on fever and inflammation, finally on life itself."[20] To-day venesection in diseases of the circulation seems to be indicated in but a single condition which may, however, appear in almost any of the symptom-complexes: "At any stage in a valvular lesion or in hypertrophy and dilatation of the heart . . . acute cardiac insufficiency may arise . . It is the one condition in which a venesection is advantageous."[21] Bleeding, then, is indicated only when it is necessary temporarily to relieve the weakened or dilated heart of the strain under which it is working. The mechanical indication and the mechanical action of bleeding both have been made clear through the discovery of the circulation and the part the heart plays in its maintenance. We no longer hear of bleeding practiced for its "derivatory" and "revulsive" actions.

More is heard to-day of a treatment which is just the converse of venesection, although it is practiced in many conditions to accomplish the very objects that were sought in blood-letting. The use of transfusion as a therapeutic measure was suggested in mythical times as a means of restoring youth. "An experiment which had hitherto only been made in animals,[22] transfusion was first put into practice by Cardanus in the fifteenth century. The attempt did not succeed, however, because, when artery was united to artery, the direction of flow was beyond the control of the surgeon. With the discovery of the circulation, the mechanical requirements of transfusion became clear.[23] Within less than forty years Lower succeeded in transfusing animals by passing the blood from an artery into a vein. And one year later Denis and King, working independently, successfully transfused blood from a lamb into man. The time was not, however, ripe for the practice of transfusion as a therapeutic measure. Unforeseen difficulties arose such as intravascular clotting, clotting at the point of union, and hemolysis. One by one, however, and almost exclusively through animal experimentation, these difficulties were cleared up and then eliminated. The successful efforts to remove what now appears to be the last great difficulty, namely, clotting at the point of union, are fresh in the minds of all. Through the use of a method brought to light by animal experiments (Queirolo, Crile);[22] of uniting blood-vessels with a tube in such a way that the blood does not come into contact with any foreign surface, or through the use of vessel suture as developed by the experiments of Carrel,[22] clotting is no longer to be feared.

[22] Crile: *Hemorrhage and Transfusion*, *1909.*

[23] I here follow the account given in Neuburger and Pagel: Handbuch der Geschichte der Medizin, iii, 87.

Transfusion of blood is used at the present time, however, only as a means of last resort. In most cases the infusion of a salt-solution into the blood vessels accomplishes the same end. The use of this therapeutic measure was suggested by Goltz when he called attention to the fact that the danger of sudden large hemorrhages depends on the emptiness of the heart, which, in that state, cannot do its work efficiently.[24] Then, after experiments on animals by Cohnheim (1869) and by Kronecker and Lauder (1879) had demonstrated that the injection of an aqueous solution of sodium chlorid may save the life of an animal which has certainly sustained an otherwise fatal hemorrhage, the measure was tried in surgical and obstetrical practice with the life-saving results that are familiar to all.[25]

Attention should here be called to the fact that transfusion and infusion experiments represent the first attempts at intravascular medication, a measure that was thereafter extensively employed in the laboratory but which has only recently come into vogue in the practice of medicine.[26]

Under the caption of mechanical methods of treating cardiovascular disease may also be included resuscitation by means of massage of the heart of subjects in whom the heart has stopped. In the ultimate analysis this method of treatment rests on the fact that the heart acts as a force-pump and that the pumping action of the heart muscle can be replaced for a time by that of the hand of the operator. More specifically, however, direct massage of the heart was first practiced by Schiff, who by this method succeeded in reviving dogs that had been killed with chloroform (1874). The measure was tried in the clinic six years later.[27]

The drug treatment of diseases of the circulation has been incalculably furthered by means of experiments on animals, while many of our most useful drugs have been discovered in experiments which were based on a knowledge of the physiology of the circulation.

The medicinal properties of digitalis, the most valuable of heart remedies, were known to the laity and the drug was used by the medical profession long before it was investigated in the laboratory. "The celebrated work of Withering on digitalis, published in 1785, shows," however, "that many deaths were undoubtedly due to the use of digitalis. Indeed, at that time and for half a century thereafter the action of digitalis on the heart and blood vessels was very imperfectly understood."[28] Traube's experiments and clinical observations on the action of digitalis did much to increase its use in disease.[29] Without going into this subject in any greater detail, the dependence of the physician on practical facts brought to light by means of animal experimentation may be shown merely by giving, in the words of one of the greatest of living clinicians, the main contraindications to the use of digitalis: "It may be said broadly to be contraindicated in all forms of heart disease without symptoms of muscle weakness" and "in states of high arterial tension . . . . . ."[30] The physiologic basis of these physiologic contraindications is so clear as to require no comment whatever.

In the choice of a heart remedy the physician has likewise to be guided by animal experiments. Both digitalis and strophanthin, for example, "act on the heart and on the blood-vessels, but in different degrees, and these differences alone determine whether one or the other shall be used in a given condition. Such differences cannot be determined except by means of animal experiments.[28]

The use of atropin in cases of overaction of the vagus mechanism is likewise based entirely on experiments on animals.

All of the drugs used as vasodilators, such as nitroglycerin and amyl nitrite, have been discovered by animal experiments and the indications for their use in cardiovascular disease would be meaningless in the absence of facts brought to light through animal experimentation.[28] Thus, the nitrites were introduced into therapeutics by the animal experimenter, Brunton, "who advised their use in angina pectoris to relieve spasm of the arteries." "Besides, in angina pectoris the nitrites may be used in any condition in which it is supposed the arterial tension may be lowered with benefit to the economy," as in certain cases of hypertension, or in combination with digitalis when, in cases of failing heart, the vasoconstrictor action of the latter might embarrass the already overtaxed heart.[31]

The vasoconstrictor adrenalin, one of the most valuable of recently discovered drugs, was brought to light through animal experimentation.[32] Indeed this statement is true of other drugs, too numerous to be mentioned here.

Animal experimentation on the circulation has also proved of value in the standardization of cardiovascular remedies. It is by that method alone that the physiologic activity of digitalis and strophanthus preparations, for example, can be determined, it is by that method alone that the physician can be supplied with digitalis and strophanthus preparations which will be of uniform strength and on which he can positively rely.[33]

The treatment of surgical diseases of the heart has been incalculably furthered—indeed this phase of medicine practically has been opened—by the experimental development of methods of opening the thorax under a negative[34] or a positive[35] pressure. Nor should we lose sight of the fact that both of these methods have as their foundation the animal experiments of Lower and of Haller, which were the means of laying down the first principles of the mechanics of respiration.[36]

THE WIDE INFLUENCE OF THE DISCOVERY OF THE CIRCULATION

Physicians should be reminded of the fact that the discovery of the circulation has benefited not only the specialist in diseases of the circulation; it has made itself felt in practically every branch of physiology and through these branches in practically every branch of medicine. To give but a single case in point: The knowledge of the circulation as acquired through animal experimentation led physiologists to study function in isolated organs kept alive by means of an artificial circulation. Using this method von Schröder, for example, determined the role of the kidneys in the process of urea formation and elimination.[37] These experiments, by placing the treatment of diseases of the kidney on a rational basis, have been of incalculable value to the clinician.

THE LYMPHATIC SYSTEM

The lymphatic system, as tributary to the circulatory system, should perhaps receive a word of notice here. Briefly, then, it may be said that in this connection the physician owes everything to animal experimentation, since the lymphatics were discovered by Aselli (1622) in an experiment on a living animal.[38]

And, it may furthermore be added, one of the chief practical uses to which the lymphatics are put by the physician, namely, the hypodermic administration of drugs, suggested itself to Wood in 1855 through contemplation of an animal experiment performed by Müller.[39]

CAN STAMMERING BE TREATED SUCCESSFULLY THROUGH THE AGENCY OF THE PUBLIC SCHOOL?

ELMER L. KENYON, A.B., M.D.
CHICAGO

The official recognition by a department of a large American municipality of stammering as a public problem, is fraught with too great possibilities to go unheeded. Constituting as it does an initiatory effort in the United States, it is more than likely, if correctly taken and successful in its results, to awaken a countrywide movement of untold advantage to an unfortunate class of sufferers. The schools very naturally have been first to realize this problem, as they have before been the first to realize other problems concerning abnormalities in children. The educator not only comes into contact with the stammering child, but his professional attitude demands recognition of his disorder; for hindrances to developmental progress of whatsoever character are, from his point of view, to be removed, and the child graduated into the mature world unburdened with recoverable abnormalities. But since stammering children have always been in the schools, it is to the great credit of the Chicago educators that they have sought to give concrete, remediable form to this important situation.

A COMMUNITY PROBLEM

And yet the problem should, I think, be considered a community rather than a school problem. The demands for the treatment of stammering are peculiar in themselves, and do not readily fit into the ordinary school régime. The problem should be considered a school problem only in so far as the schools can be shown to be best adapted for its handling. In other words, the responsibilty of the public must not be considered to end with the capability or incapability of the schools in the matter, but calls for the creation of whatever machinery may be necessary for the treatment of the disorder. Since, however, the machinery of the schools is everywhere in operation, and since the stammering children should in the natural course of their lives be in the schools, it is desirable to utilize them, if possible, for this additional service.

The successful treatment of stammering is a specific problem involving certain requirements regardless of where or under what circumstances the stammerer is treated. He is not a normal individual, and his abnormality partakes of a multitude of variations. The instrument which is to remold the delicate mental and physical activities of a stammering child, suffering from a disorder often so intrinsically a part of the child's mental life, and one so elusive and fitful as is stammering, must be carefully considered and delicately adjusted. And this is all the more important because of the danger, not merely of doing no good, but actually, by ill-considered methods, of doing positive harm. The problem is, therefore, to be taken seriously.

The disorder is one of child development. The still young and growing boy or girl, usually between four and eight years of age, already having acquired the beginnings of speech in a normal manner, starts mysteriously a slight occasional hesitation in his utterance, and then step by step the disorder becomes fully developed. The links which connect the heretofore normally speaking child with these first significant hesitations in speech constitute the key to the understanding of the disorder. Any community effort at treating stammering which does not lay stress on this beginning period would fail in its greatest opportunity. This aspect of the problem will be spoken of again.

Each case requires study to determine whether physical abnormalities capable of interfering with successful training exist. Here enter questions of general health and of abnormalities of the peripheral speech mechanism, whether in nose, throat or chest. Each case demands also consideration of the nervous and mental mechanisms, as well as of environmental conditions, for they also may have a most important bearing on recovery. These are all medical, psychologic and sociologic problems, necessarily to be handled by the physician and psychologist.

CLASSES OF STAMMERERS

Before discussing the requirements for success in the actual work of training stammerers let us realize that varying grades of severity of the disorder, varying degrees of firmness of its fixation in the mental life of the individual and varying degrees of susceptibility to training, exist. A certain minority are destined without skilled aid to acquire relatively smooth speech while still in childhood or in early youth; another proportion are capable of self-recovery early in adult life. Having eliminated these cases one is confronted with the great majority of stammerers, those who are destined, if untreated, to undergo a nearly or quite complete life-struggle with the disorder. For certain reasons the children who are capable in the long run of self-recovery should themselves be carefully treated, first, because training alone can select with certainty those that are really more easily recoverable; and, second, because the baneful hindrance to normal child development produced by stammering demands to be removed at the earliest possible moment. The permanent eradication of stammering even in the easier cases is hard enough. And any system of treatment of the whole number of stammerers should be based on the needs of the great majority of more severe cases, for the lighter ones will fall readily into such a system; whereas if plans are formed from the standpoint of the lighter cases even these may not be adequately reached, while the great mass of the stammerers will not merely be not benefited, but more probably will actually be harmed.

[39] Wood: A New Method of Introducing Medicines into the System, Month. Jour. Med., 1855, xx, 183.

QUALIFICATIONS OF TEACHERS

As to the demands of training itself, the direct work of guiding the stammerer out of his spasm-wracked utterance into a smooth speech—so far from being easy, is in the majority of cases extremely difficult. Consequently the teacher for this duty must be more carefully selected than for the ordinary work of teaching. She must be thoroughly capable, must be carefully trained, unusually enthusiastic, and possess unlimited patience. And the oversight of her work by those capable of understanding all its difficulties must be more frequent and painstaking than that for ordinary teaching. Few teachers would for long keep up their enthusiasm in work which makes such exactions, or be able to meet the inevitable difficulties, unless steadied, encouraged and assisted by one having a broader knowledge and deeper insight than most of them can hope to attain in this work. And the need of care in the selection of teachers is doubly emphasized when one approaches the practical and varied psychologic insight involved in the inculcation of self-confidence, of courage, of persistence, and the firmness in self-control on which success very largely depends.

MANAGEMENT

But all of these necessities having to do with the training of the stammerer are attainable in the public schools. There still remains a difficulty, however, not so easy to satisfy. Educated self-control, persistent, firm, habit-creating, is the key-note to success in the treatment of stammering. Bearing in mind that but one-fourth, or, at most, one-third of the child's waking hours are spent in the school room, and bearing in mind that self-control in a child under, let us say, thirteen years, especially if it be difficult self-control, is proportioned to the direct watchfulness exercised over him, one cannot but realize the great difficulty of uprooting this deeply seated disorder in the schools. Think of the difficulty under similar circumstances of causing a right-handed child to become by training left-handed, and you have a conception of the difficulties involved. The uncontrolled periods would be apt to serve to offset effectually the gains of the controlled periods. It is indeed a most serious question whether under conditions in which almost continuous discipline seems to be of vital importance, discipline during one-third of the time can be made to suffice. In the lightest cases the pupils would be benefited and eventually would recover; some of the moderate ones would probably succeed; but hope for success with the great mass of stammerers would, I think, hardly be warranted.

To overcome this serious drawback three possible things may be done.

1. Treatment may be extended over an unusually long period.
2. Parents may be systematically educated to enforce control intelligently at home.
3. A residence where the severely affected pupils might be housed day and night and kept continuously under observation could be created.

Indeed, it seems desirable that all of these expedients should play a part in the system. The relative ease with which long continued training could be secured is one of the great advantages of treatment in the schools. And while the cooperation of parents of a sufficiently intelligent character would be lacking in a large percentage of cases, yet this possibility in the system is deserving of the utmost emphasis. A systematic plan for the education of parents in the handling of their stammering children at home should be one of the prominent features of the method. Incidentally such cooperation is capable of saving a large sum annually to the community which attempts the public treatment of stammering.

SEGREGATION

Equally important is a home for the continuous residence of selected pupils. Carry out a plan of purely school treatment as rigidly as you may, yet many stammerers (I fear a large percentage) will prove to be incurable by it. Long lapses in self-control—from Fridays until Mondays, for example—will prevent success in many; weakness of will, extreme sensitiveness, unusual excitability, other abnormal nervous states, severity of manifestation in individuals, deficiencies of home environment, and especially the youthful age of the stammerer, will all play a part in producing failures. Such pupils demand the continuous molding influence of leaders capable of inspiring attention and compliance, and of skilled trainers capable of meeting every individual difficulty. There is no way, so far as I am able to forsee, to fully meet the demand of the problem without this continuous residence adjunct. The child would pass back and forth between the residence to the classroom and *vice versa*, instead of between the school and his home. Let it be realized that in case the problem of treating stammering were to be approached by any community without considering the public schools as a means for that purpose, the first necessity would be such a residential institution as I have mentioned. Thus, through the utilization of the schools, and the employment of such a residential adjunct, the whole expense of treating the disorder would be placed at the lowest possible point. From the point of view of government bookkeeping it seems hardly proper to charge up the expense of this especial institution to the school fund, but more properly it might be charged to an especial fund created for the purpose.

Successful handling of the problem of the stammerer in the public schools, then, seems feasible and desirable. Success will depend on the full grasp of the difficult nature of the problem. It will involve not only adequate instruction and training by selected teachers, but also full cooperation and direction by skilled physicians and psychologists, adequate supervision, and the institution of certain adjuncts to the regular school machinery, particularly the education of parents and a continuous residental home for selected cases.

UTILIZATION BY THE SCHOOLS

The utilization of the schools moreover, possesses certain inherent advantages. The first and most important of these is the possible reception of stammerers almost at the very beginning of the disorder. The stammering child under such a system needs not to await the attainment of usual school age before presentation at school, but with the enlightenment of parents may be presented whenever hesitation in speech becomes apparent. After the first few years every stammerer would be seen when he first entered school, and, as the years went on, a larger and larger proportion would be seen at a very early period after the inception of the disorder. The possibility and practical advantage at getting at the inciting causes would be unusual. And it is fair to presume that in the majority of cases incipient stammering could actually be arrested before the habit had become firmly fixed in the mental life of the child. Consider the saving in money, in effort, in character, in individual education, in mental suffering, and in successful lives, and such a possibility becomes of extreme importance.

Another advantage in the utilization of the schools for the public treatment of stammering would lie in the enevitable reception of nearly all stammerers, for nearly all children go to the public schools. And, also, it would lie in the permanence of the hold the system would have in each case. Only those who know the dogged tenacity of this disorder can realize the importance of such long-continued watchfulness and control.

The following suggestions are offered rather to open up the question of certain detailed methods which might be employed than as settled opinions, and they have reference in part to beginning efforts, when, as is the case in the Chicago schools, funds are apt to be inadequate.

A TENTATIVE PLAN

Scattered through the grades there would naturally be found a considerable number of fully developed stammerers offering more or less serious individual difficulties. In the practical attempt at the start to get at so extensive a problem these older cases might be passed over and the facilities available concentrated on the few lowest grades from kindergarten up. Having approached the problem through the incipient cases the full development of a system for all the stammerers could be made to accord with the success or failure in arresting the disorder in those already treated. The young stammerers who failed to respond to the more general measures first adopted would be taken one by one and together made the occasion of further steps in the development of the system. I am strongly disposed to emphasize treatment of the very beginners, to stand or fall, as it were, on the ability of a proper system to head off and to arrest a still incipient disorder. To this end the stammerers, as has been said, could be brought into the classes, so far as possible, before the regular school age. Especial attention could then be given to the study of exciting causes, and the treatment carried out, as far as possible, from that point of view.

In so far as practicable it would seem best to bring these beginning stammerers together from a number of schools into classes composed wholly of stammerers. Thus the most favorable conditions could be secured, and economy of time and expense encouraged. How the problem could be worked out with a few beginning stammerers in each school, in case it were impracticable to unite the cases from several schools, is hard to say.

If the grade teachers were capable of instituting general vocal training, including instruction in breathing, in chest control and in clearness of enunciation, perhaps with musical adjuncts, their cooperation with the especial stammering teachers could be utilized to advantage, for they, under those circumstances, could keep intelligent watch over the stammerers during the entire school period. But the plan of segregation, with the continuous care of a small class by especially trained stammering teachers seems much more likely to succeed.

The following suggestion is mentioned as a possible means of overcoming a practical difficulty connected with segregation. Let the plan of treating the stammerers by the schools be put forward at first, not as a universal proposal, but as an especial opportunity to be taken advantage of or not as the parents elect. Then let centralized schools be chosen for carrying on the work in the best and most economical manner possible. In this way there would be provided the needed opportunity to work out and prove a successful plan. Ultimately, as the public became convinced and funds became available, new centers could be created and finally all children provided for.

CONCLUSION

A practical degree of success in the treatment of stammering in the public schools seems possible, and yet one approaches the problem with profound respect. To a certain extent the road to success must be created through experience. With the determination to meet, as far as possible, the conditions of success, however exacting, the outcome must at any rate be as successful as the intrinsic conditions permit, and that degree of success would, I believe, be gratifying.

It means very much in possibility that this proposed plan for the public treatment of stammering should be studied and tried out. It means so much that failure would be a serious calamity. The wisest plan, from every point of view, as it seems to me, would be to concentrate the beginning efforts on a relatively small number of cases, to work out plans with great care, and to advance the system only in the light of painstaking trial and observation. The whole country would be the gainer from such an effort, and Chicago might well be proud to have made it. It could not but result in added knowledge which would aid greatly in the final solution of this difficult community problem.

PAROXYSMAL TACHYCARDIA*

HERBERT M. RICH, M.D.
DETROIT

Variations of the rhythm of the heart-beat occur in many pathologic conditions and are frequently seen in medical practice. In recent years a great impulse has been given to the study of these phenomena. Certain clinical types have been differentiated. Among these is a condition now generally known as paroxysmal tachycardia. At first quite widely and loosely applied to periodic attacks of rapid and irregular rhythm, it has more lately been confined to those cases of periodic tachycardia in which the heart attains a rate of 200 or more within a short time following the beginning of the attack. The clinical picture is one simply of tachycardia, it being very unusual for any irregularity of rhythm to occur. An attack of this kind is, of course, always alarming, and it is extremely important that its nature be recognized in order that suitable treatment may be instituted.

The unsatisfactory accounts of this disease in most text-books and the importance of its recognition are my reasons for considering the subject. For example, it can easily be imagined with what solicitude I watched the patient in the following case through the first attack which I saw.

History.—M. C., aged 29, a nurse-maid, was first seen in December, 1907, complaining of headache, dyspnea and dysmenorrhea. Patient had had typhoid fever at 14; several attacks of tonsillitis and several attacks of acute arthritis. In 1904 she first noticed dyspnea. I found a mitral stenosis, early stage, when she first came to me. The murmur has at times assumed a musical character. In 1902 the patient was operated on, having a resection of an ovary. Later an abscess opened, and still later a ventral hernia closed up. In April, 1909, she had a complete hysterectomy. During the time I have had the patient under observation she has had numerous attacks of incompensation of her valvular lesion. These have all ended favorably with rest and strophanthus.

---

* Read before the Wayne County Medical Society at Detroit, Mich., February, 1910.

Examination.—On Oct. 9, 1908, she came to my office. When I attempted to count her pulse at the wrist, I was quite unable to do so. Hastily putting the patient on a couch, I counted the apex-beats with a stethoscope, and found the rate to be 220, and perfectly regular. Patient said that just as she entered my waiting-room door, her heart gave a sudden "flop" and she had been conscious ever since that it had been beating very rapidly. She was pale and somewhat short of breath, but walked out to my automobile, was driven home a mile and a half, walked up to the second floor, undressed alone and went to bed.

Course of Disease.—The attack lasted seven hours, ceasing as abruptly as it began. When it stopped the patient was very dyspneic and faint and thought that she was going to die. This passed off in a few minutes and except for exhaustion the patient felt perfectly well. The next morning she was able to go about her work as usual. There was absolutely no assignable reason for either the onset or cessation of this particular attack. She has had ten or twelve attacks in three years, each lasting from thirty minutes to nine hours. I have seen her in only two of these attacks, although I have seen her many times for other complaints. She had one while in Harper Hospital, convalescent from an operation. She had one at Port Huron and was seen, I believe, by Dr. Stockwell. The mitral murmur and thrill, which are ordinarily distinct, in her case could not be detected during the tachycardia. During the second attack in which I saw her, I made sphygmographic tracings from the radial artery, but unfortunately lost them. The record was "saw-tooth," perfectly regular, very similar to one published by Mackenzie.[1]

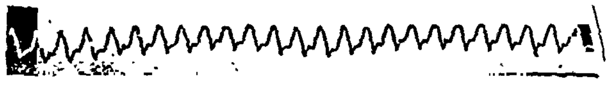

Fig. 1.—Sphygmographic tracing of radial pulse taken during an attack of paroxysmal tachycardia. Pulse 220.

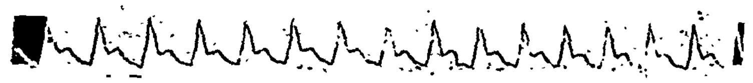

Fig. 2.—Sphygmogram of same patient taken between attacks. Case of mitral stenosis. Rate of pulse, 90.

SYMPTOMS

In general the attacks come on suddenly, usually without warning of any kind, and almost invariably without relation to any recognizable premonitory signs. The first intimation of the attack is usually described as a "flop" of the heart, and the tremendously increased rate is started almost instantly. The onset has been observed in a few cases and three or four extrasystoles have been observed before the greatly increased rhythm began. This, however, is not constant. There follows a sense of pressure over the precordial area, and almost invariably an inclination of the patient to sit down. Marked anxiety is shown, which usually passes off as the patients become accustomed to the attack and find that they have no pain and are not going to die immediately. The patient prefers a horizontal pose. The face is usually pale. Profuse sweating has sometimes occurred, but is unusual. Duration of attacks varies from a few hours to six or eight weeks. Usually there are no murmurs, the sounds of the heart corresponding to the fetal type. There may be greater or less depression, depending on the strength of the heart muscle. Patients show always a strong inclination to avoid exertion, although they apparently do not increase their discomfort by moving about, except a certain shortness of breath. Thus, my patient rode in from Pontiac on the trolley-car during an attack and then took the street-car three miles out to her residence, and apparently suffered no ill effects from it, although she was badly frightened.

The end of the attack is usually as abrupt as its onset. There is another "flop" and a feeling of goneness and suffocation with a subjective impression of impending death. This passes off in a few minutes, however, and except for exhaustion, the patient feels as well as before. In cases long continued, and especially those in which the heart was weak in the beginning, signs of stasis may occur; dyspnea, cyanosis, edema, cold extremities. Even in cases in which death was apparently imminent, sudden cessation of the attack has occurred, with prompt relief of all the extreme symptoms.

ETIOLOGY AND PATHOLOGY

It has not as yet been possible to produce paroxysmal tachycardia by any experimental procedure on the nerve-supply of the heart. Mackenzie, who has studied this condition and had autopsies performed on a number of these patients, designates this action of the heart as "nodal rhythm." An explanation of this term requires the consideration of the recently changing theories concerning the origin of the heart-beat.

For many years what is known as the "neurogenic" theory held complete sway among physiologists. This theory went on the assumption that the heart-beats originated in ganglion cells of the nervous system and were carried through nerve tissue to the muscular tissue of the heart, and that the function of the heart-muscle itself was simply that of contraction. Modifications in this theory were made to correspond to increasing knowledge, anatomic and physiologic. Latterly it was taught that the heart rhythm originated in the ganglion cells present in the heart and was distributed by nerve fibers to the heart muscle. The inhibitory influence of the vagus and the opposite action of the accelerator nerves were discovered and fitted in perfectly with this theory. Two objections, however, were brought forward. In the first place, some parts of the heart, like the apex and the aortic bulb, contain no ganglion cells. They can be made to beat rhythmically, however, under proper conditions after having been separated from the rest of the heart. The second objection was that in some animals pulsations of the heart appear in the embryo long before there are any ganglia in the tissues of the heart. For example in the chick the pulsations of the heart are noticeable in thirty-six hours, but the heart contains no ganglia until the sixth day.

Finally Gaskell, in experimenting on the heart of a tortoise, found that he could cut all the nerves without interrupting the rhythm of the heart so long as the venmuscular connections between the sinus and the ventricle were undisturbed. After cutting the muscular connections the ventricles stopped and then started again, beating with a rhythm different from that of the auricle.

In 1893 a very important contribution to our knowledge of these facts was made by the discovery of the bundle of His. This consisted of muscle fibers passing from the right auricle into the auriculoventricular septum, and sending branches out into both ventricles. The muscle cells in this bundle differ in structure from the other muscle fibers of the heart, being embryonic in character; that is to say, they are apparently the remains of the primitive cardiac tissue. The location of this bundle I have sketched in the drawing (Fig. 3).

---

[1] On March 4, 1910, the patient was seen in a typical attack of paroxysmal tachycardia, and the accompanying tracing was taken at the time. The pulse was 220, the patient anxious, short of breath, slight sweating, more comfortable sitting than reclining. Apex two fingers outside nipple line. No first sound; usual thrill and murmur absent. Attack lasted seven hours. When rhythm returned to normal, patient was unconscious for several minutes, but next morning was able to do her work as usual.

Later, Tawara, a Japanese investigator, separated a complicated net-like nodule from the rest of the fibers of the bundle of His, and this is now known as Tawara's node, or the atrioventricular node. Later Keith described a second node similar to Tawara's situated at the juncture of the superior vena cava and of the auricle. Tawara's node is in the auricular part of the bundle of His. These nodes receive special arteries, and are now looked on as the seat of the impulses of the heart-rhythm.

The modern or myogenic theory of the heart-rhythm is that the impulses arise in and are transmitted by this primitive cardiac tissue known as the bundle of His, which is composed of muscle cells embryonic in character. In particular it is believed that normally the impulses arise in the node of Keith. The experiments previously referred to, however, in which the ventricles started up with an independent rhythm after both nerve and muscle connections were cut, are taken to prove that Tawara's node alone also may originate impulses capable of producing ventricular impulses. All these, of course, are subject to inhibition and acceleration by the well known nerve channels.

The nodal rhythm of Mackenzie rests on the assumption that for some reason the impulse begins in the node of Tawara instead of Keith, thus reversing the normal sequence of contraction, or even in some cases, he believes, there seems to be no auricular contraction whatever. The nodal rhythm is found not only in paroxysmal tachycardia, but also in various arrhythmias. The change in the origin of the impulse might occur through one of two means, either the impulse from the auricle is interrupted in its transmission to Tawara's node, and the latter being independent takes the lead, or through disease Tawara's node becomes more sensitive and originates impulses at a rate which interferes and possibly overcomes the auricular impulse.

In two cases of paroxysmal tachycardia which had been observed for several years by Mackenzie, Keith found areas of fibrosis of the myocardium with distinct evidences of cellular changes in the bundle of His. In one case he found total obliteration of the lumen of the artery supplying the bundle and probable degeneration of the cells of the bundle. The pathology known then is a fibrosis and degeneration of cellular elements in the heart extending to the bundle of His in such a way as to produce the nodal rhythm. Hoover says clinical evidence tends to show that paroxysmal tachycardia may result from disease of the medulla or reflexly through the medulla, from affections of the vagi, and from myocardial disease. Pal believes that it may be due to vasomotor relaxation in the splanchnic vessels.

The inability of investigators to produce the condition experimentally is interesting, and many observers have declared the condition a pure neurosis. This conclusion, however, seems hardly justified by our present knowledge. Apparently inhibition is suspended and instead of receiving successively phases of contraction, relaxation and rest, we have a condition approaching embryocardia.

The influence of position in these cases is marked and interesting. Some subjects can stop attacks by standing head down and feet up in a corner. One patient could stop it by leaning forward with the arms hanging down. In the case reported to-night two attacks came on while the patient was leaning over with the arms extended making a bed, and one while putting on a nightdress with the hands high above the head. Hoover relates the following interesting experience:

> A woman aged 35 years had had many attacks of tachycardia during the past ten years, averaging about three or four a year. There has been a very constant relation between nervous or emotional excitement and the attacks. The common sequence of events has been, constipation followed by accumulation of gas in the stomach and bowel, several sleepless nights, and then the attack of tachycardia which sometimes began with the "heart-flop" and at other times the tachycardia was in full force before any warning of any kind was perceptible. She had learned to bear these attacks with equanimity and no longer permitted them to interfere with attendance on her household duties, as she experienced no severe discomfort. Never before had a paroxysm of tachycardia lasted more than eight hours, but in this instance it persisted twenty-eight hours. The patient had been operated on two weeks before for suppurative salpingitis, and both tubes and ovaries were removed. A daily rise of temperature as high as 101 persisted after the operation. The pulse-rate remained between 100 and 120. The preceding day tachycardia commenced without the slightest warning or any unusual experience. The pulse-rate was 240 per minute, and so small at the wrist that no tracing could be obtained. The heart dulness was increased one and one-half inches to the right of the sternum and one inch external to the nipple line. There was a large centrifugal pulse visible in the external and internal jugular veins which had the same rate as the carotid pulse. It was impossible to determine by inspection the time relation between the jugular and the carotid pulse, but the two tracings taken with the Jacquet polysphygmograph show very clearly that the jugular pulse alternated with the heart and with the carotid pulsations. There were no signs of stasis in the liver or extremities. There was no cyanosis or dyspnea. Embryocardia was well pronounced. The tracings show the correlation between auricular and ventricular contractions as undisturbed. Pressure on the vagi, compression of the abdomen, and holding the glottis closed after deep inspirations had no effect. The patient was then taken out of bed and held with heels up and head down for a minute without result. She was then instructed to take a deep inspiration and "bear down" while in the inverted position. In a few seconds the heart-rate suddenly changed from

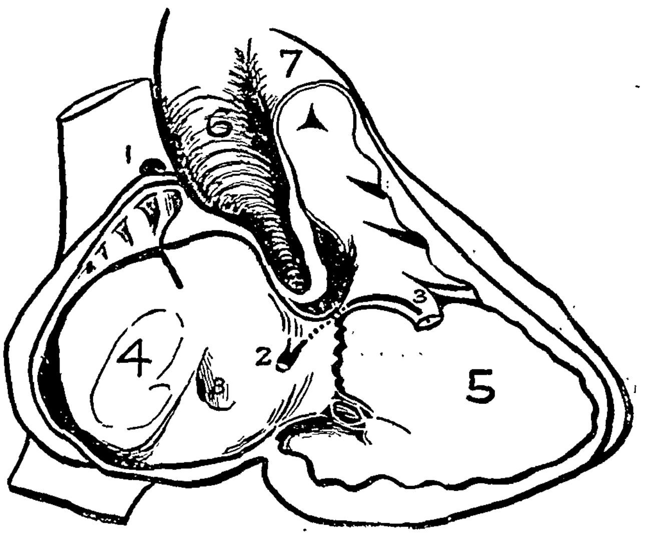

Fig. 3.—Diagram showing position of a portion of the remains of the primitive cardiac tissue, including the nodes of Tawara and Keith. 1. Superior vena cava and node of Keith. 2. Auriculoventricular node of Tawara, from which the auriculoventricular bundle arises. 3. Right division of the auriculoventricular bundle. 4. Right auricle. 5. Right ventricle. 6. Aorta. 7. Pulmonary artery (after Keith).

240 to 120, the rate which was in force at the onset of the tachycardia. The tracings and the exact halving of the heart-rate at the end of the attack show it to have been caused by the liberation of a series of extrasystoles from the auricle, all of which were transmitted to the ventricle. Vasomotor dilatation in the splanchnic area was probably not the cause of this attack. Had that been the case, inversion alone would have sufficed to arrest the tachycardia. The additional factor (viz., forced expiratory effort with closed glottis after a deep inspiration) was required to stimulate the bulbar inhibitory center sufficiently to arrest the series of extrasystoles. The heart-volume returned to the normal boundaries immediately after the tachycardia ceased.

DIAGNOSIS

The diagnosis of paroxysmal tachycardia is usually not difficult. The rate is much higher than in other tachycardias, such as accompany fevers and thyroid diseases. While cardiac dilatation occurs in many cases of this disease, it is accompanied by no arrhythmia unless in the very latest stages. There may be difficulties in the diagnosis of periodic arrhythmia from myocardial disease. In general, however, a pulse-rate over 200, regular, and apparently not the termination of a long period of incompensation, may be pretty certainly set down as paroxysmal tachycardia. Mackenzie states that it occurs as a rare complication of mitral stenosis and aortic insufficiency.

TREATMENT

What has been said concerning the influence of position in these attacks is undoubtedly the most important element of treatment. I have never succeeded in influencing an attack in this way, but apparently it has been done and will often succeed. The simplest device is to put the head down and the feet up, which can usually be done easily on an operating-table or a hospital litter. If there is no dyspnea or cyanosis, the abdomen may be tightly bandaged. Compression of the vagus in the neck has been successful, and the electric current over the vagus may be tried. Ice over the heart or at the nape of the neck should be useful at times.

Drugs seem to be of little value. Mackenzie states that after many year's experience he has decided that his drug treatment has no effect on the attacks themselves. Proper treatment between attacks is, of course, very important. Abstinence from stimulants is important and gastro-intestinal insults should be avoided. In cases in which the blood-pressure is high, persistent measures should be taken to reduce it.

CONCLUSIONS

1. Paroxysmal tachycardia is a term applied to cases in which the nodal rhythm is transient and recurrent.
2. It may occur as a complication in mitral stenosis and aortic insufficiency.
3. While its onset is alarming, the individual attacks usually terminate in recovery very promptly, and this fact necessitates great caution in the prognosis of the disease.
4. Treatment of the individual attacks consists almost entirely in physical therapy by position and external applications. Proper general treatment between attacks is indicated.

Congenital Edema of the Leg.—At the time of the birth of a female child there was noticed a well-marked edematous swelling of the sole and dorsum of the right foot and a swelling of the leg on its front and outer aspects which had continued. The right leg was one-half inch longer than the left, measured from knee to heel. It was believed that a deep angiomatous condition could be excluded.—Maynard Smith, in *Proc. Roy. Soc. Med.*, March, 1910.

A MODIFIED SIMPSON'S TAMPON TO PREVENT NASAL HEMORRHAGE *

MARK D. STEVENSON, M.D.
AKRON, O.

It sometimes becomes necessary to use mechanical means to stop nasal hemorrhage, spontaneous, following operations, or due to any of its many causes. After most nasal operations the patient should be kept in bed in a hospital for a time, but if this ideal condition cannot be fulfilled and the patient has to go home or some distance from the operating room, away from skilled attendance, it is safer to tampon the nares. I will describe a very easy and efficient method of tamponing the nose, which requires but a moment for its performance and is less distressing than packing by gauze or other material. The ordinary treatment of epistaxis by cauterization, etc., will not be considered in this paper.

Rest in bed, the quiet assurance of the nurse or physician that the bleeding will cease, which it practically always does when the blood pressure is sufficiently lowered, ice to the face or neck, hot water bottles to the lower extremities, and, if necessary, to the lower parts of the body, nearly always succeed in stopping the bleeding. The patient should be turned on the side from which the nose is bleeding, so that the blood may drip directly into a pus basin or towel and not compel him to clear the throat of blood or otherwise in any way disturb the clot. The clot is Nature's effort to prevent the hemorrhage and should be conserved.

I think the application of drugs usually accomplishes little more than to disturb the clot. Peroxid of hydrogen, solutions of cocain, and especially adrenalin, help to prevent or to stop immediate hemorrhage, but I think there is greater likelihood of after hemorrhage than if they had not been used. I do not put as much confidence as some do in the use of the calcium salts before an operation.

After a nasal operation, if the patient cannot be kept in a hospital, it is often advisable to tampon the nasal cavity. I use a tampon composed of compressed cotton, a modification of Simpson's tampon. I found the Simpson tampon too small, so I had larger ones made. They are three inches long and one-half inch wide by one-sixteenth or one thirty-second inch thick; when moistened they swell until very much thicker. The cotton tampon must be kept dry before introducing. It should be wrapped in thin gutta percha of equal length, the gutta percha being wrapped around the tampon two or three times, much like wrapping a cigarette, and the free edge, except at the ends, gummed down by some sterile ointment, e. g., zinc oxid or 2 per cent. calomel ointment. The gutta percha tissue is easily kept clean by keeping it cut into proper sized pieces, three inches long by two and one-half inches wide, in a 1 to 2000 solution of formalin. The thin gutta percha which deteriorates in the air keeps well in this solution and should be thoroughly dried between layers of gauze before applying to the tampon.

If it is desired to plug the naris without knowing where the hemorrhage is coming from, or following removal of the inferior turbinate or a large ridge or spur low down on the septum, the long tampon is introduced into the naris and pushed horizontally backward along the floor of the cavity until entirely within the nose. The posterior end will then lie in the posterior choana. Sterile water, normal saline, compound tincture of benzoin, or some mildly antiseptic solution should then be dropped on the open end of the tampon, which will cause it to swell. Moisture may also be admitted through a few small perforations in the gutta percha. The tampon will then press evenly against the external wall of the nose and septum and occlude the posterior choana and anterior naris. The septum ordinarily is fairly elastic and gives a little so that too much pressure is rarely, if ever, felt. In a wide fossa two are required side by side. They are best introduced at the same time, although they should be wrapped separately in gutta percha, as they are then more easily removed. Occasionally one should be split and one and a half introduced or even two and a half. Experience soon teaches how many to use. In some very narrow anterior nares the full size may be too wide to introduce, or it might seem that when swollen it would be too large to remove easily. The tampons can be readily narrowed to any desired width by a strong pair of scissors. They rarely require to be shortened.

---

* Read before the Ophthalmological and Otolaryngological Section of the Cleveland Academy of Medicine, Feb. 25, 1910.

I have never had any special difficulty produced in the nasopharynx, tube or ear, after using the tampons, although in twenty-four or forty-eight hours they should be removed, as they are no longer needed. After removal of the middle turbinate or a spur high up on the septum they can be cut much shorter and introduced high up into the nasal fossa where, after moistening, they remain. Simpson's tampons which can be used in the upper portion of the nasal fossa are much too short to use in the lower part of the nose, and if two are used, one in front of the other, some difficulty may be experienced in removing the posterior one. Good, who was the first man I saw use Simpson's tampon, has also devised a much larger one, but it is so wide that, in my opinion, it could be introduced and removed through only a few of the largest nares.

These smooth surfaced tampons are easily and usually painlessly (in contrast to gauze or cotton packing) removed, preferably by an alligator forceps. Hemorrhage usually follows removal for a few moments, but if the clot is not disturbed by blowing the nose there is little bleeding. Usually the clots should not be washed out for another twenty-four hours, and only very gently at first, depending on the case. If the end of the tampon in the anterior naris is covered by swelling of the mucous membrane, after the mucus is wiped or sprayed away, a 10 per cent. cocain in adrenalin (1 to 1000) solution can be applied on pledgets of cotton, quickly shrinking the swollen tissues and exposing the often flesh-colored end of the tampon. If the septum is too freely movable it may be supported in the opposite nasal fossa by another tampon, or, if it be thought necessary to breathe through that side of the nose, by some of the pervious nasal splints or by a proper sized piece of rubber tubing. There is no distress in introducing tampons following an operation, and very little in any case. If an anesthetic has not been previously used for an operation the nares should sometimes first be sprayed with a weak solution of cocain or other local anesthetic, and adrenalin.

—**Congenital Absence of Left Femur.**—P. Lockhart Mummery (*Proc. Roy. Soc. Med.*, March, 1910) reported the case of a male child, aged 2, in which there was an absence of the left femur. The knee-joint appeared to be normal but was close up to the left hip; below the knee, the leg was normal but rotated outward. The *x*-ray shows the diaphysis of the left femur missing, the lower epiphysis being present, with a small island of cartilage above this. The child showed no other congenital defect and is healthy.

RESPIRATORY JOINT CREPITATIONS

CHARLES MINER COOPER, M. D.

SAN FRANCISCO

For many years I have occasionally heard confusing adventitious sounds over the scapular areas during auscultation of the organs of respiration. They may be of a creaking, crunching or bubbling character, and may occur during either or both phases of respiration. They are somewhat superficial and are confined to the scapular areas, or, if they extend outside, lose considerably in intensity at the bone margin. Displacement of the scapulæ forward causes them to disappear, and clear respiratory sounds are now audible when the stethoscope is placed over the same pulmonary area.

I have been able to demonstrate these sounds to students in the clinic and have hitherto listed them under the term "the scapula rub." Three well-marked cases of late have enabled me, however, to trace their origin. In all three cases they were produced in the apparently healthy shoulder-joint during its respiratory movement. From this position of maximum intensity they were propagated by the scapula to the suprascapular and infrascapular regions and by the humerus along the arm, over which they were heard with peculiar distinctness. In one instance they were propagated along the clavicle, but did not reach the sternum. In two of the three cases they had led the examiner to entertain a suspicion that the patient had tuberculosis.

I have deemed their occurrence of sufficient importance to draw attention to for the following reasons:

1. No mention is made of them in the student's text-books.
2. They sometimes lead to an erroneous diagnosis of tuberculosis of the lung area over which they are heard.
3. Physicians who devote most of their time to the treatment of tuberculosis tell me that though they have long heard similar sounds they have never been satisfied as to their origin.

It seems not improbable that similar confusing sounds may be produced in the sternoclavicular and acromioclavicular joints.

TRAUMATIC RUPTURE OF THE MESENTERY*

MAHLON D. OGDEN, M.D.

Professor of Pathology, Medical Department, University of Arkansas
LITTLE ROCK, ARK.

Most American and English authors either disregard this condition or treat it only as a complication of rupture of the intestine. In the latter form it is frequent, but rupture of the mesentery alone without other lesions in the intestine is comparatively rare. A few cases have been reported by German and French authors.

Neumann[1] reports one case in a boy run over by a wagon, the blood-vessels were ligatured and the mesentery sutured. Complete recovery followed. Neumann also collected nine cases (reported 1845-1896) in which autopsies had revealed rupture of the mesentery; the injury being due in most cases to being run over by wagons, or to falls or jumps from heights; in one case, to a kick by a horse and in one, that of a car conductor to being jammed between his car and a wagon.

---

* Read before the Pulaski County (Ark.) Medical Society, March 21, 1910.

[1] Neumann, R.: Beitr. z. klin. Chir., 1904, lxiii, 676.

Kudlik[2] reports two cases, one of a child run over by a wagon, one of a man injured in a factory; both showed rupture of the mesentery without injury to the intestine, with hemorrhage. The child recovered from the operation; the man died from peritonitis.

Autenrilth[3] reports one case, that of a child of 4½ years, also run over; the mesentery was ruptured, tearing many of the branches of the arteria mesenterica, with serious hemorrhage. The child recovered.

Laubie[4] describes an autopsy on a man who fell from a height of 15 meters and died a few hours later. The mesentery was ruptured with hemorrhage of the mesenteric artery; no other lesion of the intestines. Death was probably due to hemorrhage.

Erdmann[5] reports three cases; in two of which the mesentery was torn from the intestine; and one in which there were as many as twenty lacerations of the mesentery causing hemorrhage. Recovery ensued in all cases.

Hume[6] reports a case of torn mesentery followed by resection of a portion of the intestine and recovery.

The following is a case which came under my observation, post mortem:

History.—On July 31, 1909, about 9 p. m., the patient, P. J. I., a white man, aged 40, engaged in a fight on the street, in the course of which he either fell or was knocked down and some witnesses stated that he was kicked in the abdomen. Apparently not much injured, with the exception of a few bruises about the face, he was arrested and taken to the police station. About 10 p. m. he complained of pain in the abdomen and a physician was called. A few bruises on the face and a rapid pulse (which was attributed to his drinking) were the only objective symptoms found. The next morning (Sunday) at 7 a. m., he was removed to a hospital, still complaining of abdominal pain. His temperature was 97 F. and his pulse 70 and very weak. During the day, however, he was able to walk about the ward. At 6 p. m. his temperature was 97 F. and his pulse was 80. Sunday night he vomited several times and had to be catheterized. On Monday, August 1, at 6 a. m., his temperature was 100 F. and his pulse could not be counted. From then on his condition became progressively worse until he died at 3 p. m.

Autopsy.—All organs were practically normal. No bruises or marks on abdominal wall. The abdomen was filled with fluid blood which came from an irregular tear entirely through the mesentery. The tear was 3 cm. long, just opposite the fourth lumbar vertebra and 2 cm. from the posterior attachment of the mesentery.

I am indebted to Dr. O. K. Judd for the clinical history of this case.

A REMARKABLE CASE OF METHYL-ALCOHOL POISONING

CARL KOLLER, M.D.
NEW YORK

History.—Mrs. M. D., a Russian Jewess, was brought to the office blind on March 8, 1910, giving a history of failing vision beginning eleven days before. After an examination which led to the probable diagnosis of toxic amblyopia, the following history was elicited. Fifteen days before she had been present at a dinner, on which occasion she partook of a small quantity of whisky, about one tablespoonful. Her habits had been temperate, that is, she was accustomed to take 1 to 2 teaspoons of brandy once a day with her mid-day meal. Two days after the dinner she began to have pain over the eyeballs, more marked on moving the eyes, also headaches and some blurring of vision. The diminution of vision continued until the vision of the right eye was absolutely abolished, that of the left considerably reduced. This was three days before she was brought to me.

Examination.—With neither eye could the patient count fingers at any distance. The fields taken roughly with a visiting-card brought out the fact that there was an absolute central scotoma in the right, with some indefinite peripheric vision present, except below. The field of the left eye was similar, but with no central scotoma. There was absolute color-blindness. The ophthalmoscopic picture was that of marked papillitis in both eyes (amounting to 5 diopters in the left and 3.5 diopters in the right eye), with enormously widened and somewhat tortuous veins. Even the finer veins leading from the macula were greatly injected. The arteries were only slightly narrowed. The retina itself seemed in no way involved. The pupils were quite wide, but not fixed, reacting weakly and widening again. The general history and physical examination disclosed that the patient had been suffering from cholelithiasis for some time past. Considering the rapidly failing bilateral loss of vision, the diagnosis of toxic amblyopia suggested itself in spite of the marked papillitis and the headaches, which latter a rapidly growing intracerebral neoplasm might have explained. The brandy habitually consumed by the patient was examined by Dr. Arthur Bookman of the Mount Sinai Pathological and Chemical Laboratory and found to contain 6 per cent. of methyl alcohol. The dinner whisky could not be obtained.

Course of Disease.—In the further course of the case, during the next week, there was at first an increase in the swelling of the nerve-head with a few small hemorrhages, very narrow arteries, and still greater contraction of the field until only the upper outer quadrant in either eye remained. After another week the functional examination showed improvement in vision to the extent of counting fingers at 1 foot with either eye, and considerable enlargement of the fields, bearing out, for the first time, the report of subjectively improving vision. Objectively, the swelling of the discs had diminished, the outline being fairly well defined in the right eye and shining through the still edematous fibers in the left. After ten days more, both discs looked fairly normal and not even especially pale; except that the larger arteries were still considerably narrowed. The fields for white were roughly of apparently normal size, though no further improvement in central vision, beyond the counting of fingers at 1 foot could be noted. At the present writing, about seven weeks after the onset of the trouble, the patient's vision in each eye has improved to 20/50. The field is normal for white and for colors. The pupils react well. Ophthalmoscopically the nerves are slightly pale and the arteries less filled than normal.

The remarkable features of this case are that it occurred in a temperate woman in whom wood-alcohol poisoning would not easily suggest itself; that it was probably a case of chronic poisoning in which the addition of a somewhat larger dose brought on the acute symptoms; that only a very small quantity of the poison (about 7 to 8 grains) was ingested daily; and that the papillitis present was intense.

It is well known that methyl alcohol taken in small quantites is innocuous to many persons, whereas, on the other hand, there are many people for whom even half a teaspoonful would constitute a poisonous dose. This difference in susceptibility to the poison is probably due to the difference in secondary chemical compounds formed in the alimentary canal and the blood. At one time formaldehyde, one of these, was suspected, but this is probably not correct, nor can any admixed impurities, such as acetone, which was also accused, be made answerable.

In my patient the symptoms of cholelithiasis showed a disturbance in the function of the liver and consequent interference with digestion. It is probable that her intolerance to the small doses of methyl alcohol was due to this condition.

The ophthalmoscopic picture of methyl-alcohol poisoning appears under three varieties or degrees: first, entirely negative; second, with a well-defined pale disc and contracted arteries from the beginning, and third, as a neuroretinitis of moderate degree.

Pathologically, two structures are affected in methyl-alcohol poisoning, the ganglion cells and the blood-vessels, and probably the ophthalmoscopic picture varies according to the kind of structures involved and the degree of involvement. In the first variety, with the negative opthalmoscopic picture, the ganglion cells are primarily injured and the injury leads subsequently to the ascending atrophy of the nerve fibres.

The second picture, pale nerve with narrow arteries must be due to the effect of the poison or the respective derivatives of the poison on the blood-vessels, and is comparable to the effect of poisoning with quinin and the salicylates.

The third picture, neuroretinitis with swelling of the nerve-head and engorged veins, is either due to a real neuritis or dependent on altered circulation and pressure conditions within the cranial cavity.

In both these latter forms, there is of course the ganglion cell degeneration added to the circulatory disturbance. As a final result we find ophthalmoscopically a simple atrophy, corresponding to the first class, and a neuritic atrophy, corresponding to the second and third pictures.

POISONING BY MERCURIC CHLORID THROUGH VAGINAL DOUCHES

ARTHUR J. PATEK, M.D.
MILWAUKEE, WIS.

In discussing the various ways in which mercury, therapeutically administered, may be absorbed with toxic consequences, little emphasis has been laid on the danger attending its use in vaginal douches. The drug is surely freely used in this manner, and doubtless many individuals show a dangerous susceptibility to its irritating effect.

A recent experience with a fatal case of mercury poisoning through vaginal douches, is worth recording, so that it may constitute a warning to others. Inasmuch as several similar cases have recently been reported[1] in THE JOURNAL, the chronicling of another. even though it be a rare experience, must be considered an urgent duty.

The patient, Miss K., aged 35, first consulted me on the morning of Jan. 23, 1910. She gave a history of persistent vomiting and purging of four days' duration. Careful questioning elicited no satisfactory information, and her symptoms were without known cause. The taking of medicine in any form was denied. An epidemic of intestinal grippe was raging at the time and her condition was ascribed to this. She complained of no pain whatever, nor did physical examination elicit anything further. Powders of bismuth and morphin were given.

She was again seen January 25. Purging had ceased entirely, but vomiting followed everything taken by mouth. No pain was complained of, and the abdomen was not sensitive to touch. There was neither headache nor dizziness; vision was good. Since Jan. 23, anuria had existed. Again detailed questioning elicited absolutely no information of value, and the patient again denied having taken medicine or of even having used drugs or medicine in any form whatever. Efforts to stimulate the flow of urine were made. During the following night a small quantity was voided (after 72 hours' anuria) which, inasmuch as menstrual flow had begun, the attendant failed to save, as had been directed. On the previous day epistaxis was noted, continuing 36 hours. While during the first few days the mental condition was apparently normal, the patient occasionally lapsed into a dazed state when she remained unnoticed. Epistaxis recurred on Friday the 28th, and with the vomitus much of the swallowed blood was regurgitated. On the evening of this day four ounces of bloody urine were withdrawn by catheterization. It contained an abundance of albumin, epithelial cells, hyaline casts, blood and pus. Every effort was made to restore the action of the kidneys, but, save a slight response as indicated by a small quantity of bloody secretion, no further result was attained. The patient was in a stuporous condition during the night of Friday the 28th and the following day.

Although suspecting that the patient had taken mercury in some form, either with suicidal intent or by accident, this was strenuously denied, and no explanation for the rather characteristic symptoms of corrosive sublimate poisoning was suggested. However, on Saturday, the 29th, the day before her death, corroborative information of the suspected cause was obtained. I was reliably informed that on the day she was first taken ill, January 19, *four days prior to my first visit*, she had consulted another physician, complaining of severe irritation and burning of the labia. This physician was told that she had been using douches prepared by dissolving tablets in water, and the tablets were recognized by him as being mercury bichlorid. On examination he found a most intense inflammation and edema of the labia and vaginal tract. so much so that instrumental examination was impossible; and he noted the patient's excruciating suffering from the local condition.

Lacking evidence that the patient had taken mercury in any form by mouth, it is evident that the absorption of the poison in toxic quantities must have taken place through the vagina. The strength of the solution used is not known. In any event, this case, and others recently noted in THE JOURNAL[1], ought to constitute a warning to physicians that mercury can hardly be employed with safety in this manner.

BRONCHIAL VINCENT'S ANGINA

J. H. ROTHWELL, M.D.
LIBERTY, MO.

Vincent's angina is a disease that usually attacks the throat, especially the tonsils. The following cases, I think, will show that, like diphtheria, Vincent's angina sometimes attacks the tracheal and bronchial mucous membranes.

CASE 1.—Miss A., went to Kansas City, Dec. 7, 1909, to visit a brother, not feeling well when she left home. At 10 a. m., December 10, while down town shopping she was taken with a chill. She was taken to her brother's home and a physician called, who pronounced it a severe case of pneumonia and advised that the patient be brought to her home here.

I saw her about 7:30 p. m. Her temperature was 104 F. There was intense pain in the left side below the nipple, constant coughing, with profuse, bloody fluid sputum, and a sensation of great oppression over the upper part of the chest and a sensation of smothering. The breathing and cough resembled those of both asthma and croup. The tongue was clean and the throat not involved, no membrane or ulceration of any kind being present. I could make out no consolidation of the lung and the case did not impress me as being pneumonia. I procured some of the sputum and a smear showed it to be full of Vincent's spirilli and fusiform bacilli. This was evidently a case of bronchial infection, just as we sometimes have laryngeal and bronchial diphtheria. The next morning the temperature was normal and from that time for ten days or two weeks it varied from normal to 102 F. The characteristic breathing, cough and sputum continued, though gradually abating. The patient was able to be up in about three weeks. Six weeks later, on any exertion, such as sweeping, she would expectorate the same fluid, bloody sputum full of Vincent's spirilli, and it was two or three months before she was entirely free from them.

Case 2.—Another case was that of a woman who came to visit her sister to recuperate from an attack of grippe. After a few days I was called to see her. She was suffering with pneumonia; the infective agents at this time being the *Pneumococcus* and *Diplococcus catarrhalis*. She was a very delicate epileptic, with a very bad heart lesion, but she recovered in the usual time and went to her home. In a few days she was brought back again with a relapse, the infective organisms this time being those of influenza and *Diplococcus catarrhalis*. Every day or two during this attack she would have a seizure of severe, asthmatic coughing, with a sense of great oppression in the chest and a smothering sensation, accompanied by the expectoration of a fluid, bloody sputum full of Vincent's spirilli and fusiform bacilli. At other times the sputum did not contain many spirilli and often none. But when these attacks did come on the cough, breathing and sputum were characteristic of the former case.

These two cases were very interesting to me and similar cases have never been reported so far as I know. Altogether I have had three cases complicated with bronchial, Vincent's angina. I reported these cases to Dr. Frank J. Hall, a pathologist, of Kansas City, Mo., and he said that he had never seen any cases like them, nor had he seen any reported. Several months later, while I was visiting his laboratory, he told me that he had, a few days before, been called, with another physician, to see a patient whose case was a puzzling one, the patient having been under treatment then for six weeks, and he had found the same characteristic symptoms, viz.: the oppression of the chest and smothering sensation, and the breathing and cough resembling those of asthma and croup and the fluid bloody sputum which I had described to him as occurring in my cases. On microscopic examination, the sputum was found to contain great numbers of Vincent's spirilli and fusiform bacilli. On the strength of the diagnosis, iodids were administered and iodin in a nebulized form used. In two or three days the patient was greatly relieved. He reported that Dr. Hall said that no sign of the disease was apparent in the throat. So I am convinced that Vincent's angina sometimes attacks the tracheal and bronchial mucous membranes.

THE DIFFERENTIATION BETWEEN DEMENTIA PRÆCOX AND DEPRESSIVE STATES BY SO-CALLED BIOLOGIC BLOOD-TESTS*

ELLEN CORSON WHITE, M.D.
AND
S. D. W. LUDLUM, M.D.
PHILADELPHIA

While the Wassermann reaction is of greatest value in differentiating between syphilis and non-syphilitic diseases of the nervous system, it does not permit of further differentiation between so-called functional nervous diseases.

Recently Much published a description of a method by which, he believed, he could differentiate dementia præcox and manic-depressive disease from other diseases. The method is based on the inhibiting action of blood-serum in cobra hemolysis. His results have not been confirmed by others.

In the following we wish briefly to state that we seem to have been able to differentiate by relatively simple methods between dementia præcox on the one hand and melancholia on the other.

Our method is based on the determination of the fixation of complement of guinea-pig serum by the serum of the patient. We found that in melancholia the amount of complement absorbed is very much larger than in all other diseases that we have encountered, and also much larger than in dementia præcox, in which disease it is approximately normal.

We have tested 67 cases of various mental diseases, 37 cases of melancholia half of which were of the manic-depressive type, and the others involutional. So far our test has been decisive and characteristic in all cases examined. We shall continue the examination for possible exceptions.

We also wish to state that it is possible to differentiate more clearly between mental diseases by using very carefully standardized factors in Much's method. In our cases this reaction always occurred in dementia præcox and almost never in melancholia, when all the factors were standardized.

In conclusion we wish to say that our results distinctly indicate that in so-called functional mental diseases, chemical changes in the blood take place, and can be discovered by so-called biologic methods.

216 South Fifteenth Street.

* Preliminary Report from the Laboratory of Neuropathology in the University of Pennsylvania.

ILEUS, DUE TO MECKEL'S DIVERTICULUM

ATTACHMENT OF TERMINAL LIGAMENT TO MESENTERY MAKING RING, THROUGH WHICH ILEUM FORMED A HERNIA WITH STRANGULATION

C. E. HARRIS, M.D.
BLOOMINGTON, IND.

History.—W. F. N., male child, aged 2, up to Dec. 23, 1909, had had no serious illness. About 3 a. m., December 23, the child awoke and seemed to be in great pain. Half an ounce of castor-oil was given by the parents. About 5 a. m. the child began vomiting. Pain and vomiting continuing, a physician was called about noon. He prescribed calomel and more castor-oil, but everything given by mouth was rejected. On the second day several enemas were given, and, excepting a very small stool following the first enema, neither feces nor flatus passed. There had been no mucus nor blood passed per rectum. Pain, vomiting and absolute constipation had been continuous from the beginning of the illness. I was called on the evening of the fourth day and found that the child had died a few minutes before my arrival. I asked for an autopsy and the privilege was granted.

Autopsy.—Hippocratic facies marked; abdomen greatly distended. On opening the abdomen several greatly distended coils of small intestine presented. The intestine had lost its luster and was very dark in color; the mesenteric vessels were engorged. Folowing the small intestine downward, I found several collapsed coils massed in the ileocecal region. Here I found a band surrounding the intestine, above which the bowel was greatly distended, and below, it was collapsed. The appendix was in a normal condition. I tied off the cecum a short distance above the ileocecal junction and the ileum just above the constriction, removing the specimen. On examination it proved to be a Meckel's diverticulum, 2 inches in length, 3/4 inch in breadth, arising 14 inches from the ileocecal valve, with a terminal ligament attached to the mesentery directly opposite its base, forming a ring through which the ileum had become herniated.

New and Nonofficial Remedies

SINCE THE PUBLICATION OF THE BOOK "NEW AND NONOFFICIAL REMEDIES, 1910," THE FOLLOWING ARTICLES HAVE BEEN ACCEPTED BY THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION. THEIR ACCEPTANCE HAS BEEN BASED LARGELY ON EVIDENCE SUPPLIED BY THE MANUFACTURER OR HIS AGENT AND IN PART ON INVESTIGATION MADE BY OR UNDER THE DIRECTION OF THE COUNCIL. CRITICISMS AND CORRECTIONS TO AID IN THE REVISION OF THE MATTER BEFORE PUBLICATION IN THE BOOK ARE ASKED FOR.

THE COUNCIL DESIRES PHYSICIANS TO UNDERSTAND THAT THE ACCEPTANCE OF AN ARTICLE DOES NOT NECESSARILY MEAN A RECOMMENDATION, BUT THAT SO FAR AS KNOWN IT COMPLIES WITH THE RULES ADOPTED BY THE COUNCIL.

W. A. PUCKNER, SECRETARY.

(*Continued from page 1789*)

MAMMARY SUBSTANCE—Armour.—Mammary Substance—Armour, consists of the mammary gland of the sheep freed from fat, cleaned, dried and powdered, without the addition of preservative or diluent.

A yellowish to orange colored powder, having a slight peculiar odor. Only partially soluble in water.

One part represents approximately 4½ parts of the fresh mammary gland of the sheep. It contains nucleoproteid which, when treated with dilute sulphuric acid, yields guanin. (S. Fränkel. Descriptive Biochemie, p. 386). Upon incineration, it should not yield more than 9 per cent. ash.

Actions and Uses.—See Mammary Gland (N. N. R., 1910, p. 141).

Dosage.—0.13 to 0.3 Gm. (2 to 5 grains) three times daily.

Manufactured by Armour & Co., Chicago. Not patented or trademarked.

Mammary Substance Tablets-Armour.—Each tablet contains desiccated mammary substance 0.13 Gm. (2 grains).

Dose.—1 to 3 tablets three times a day.

DESICCATED SPLEEN—Armour. — Desiccated Spleen—Armour, consists of the spleen of the calf, freed from fat, cleaned, dried and powdered, without the addition of preservative or diluent.

A dark yellowish colored powder, having a peculiar odor. Partially soluble in water.

One part represents approximately 4¾ parts of the fresh spleen substance. It contains nuclein and iron. Upon incineration, it should yield not more than 7 per cent. ash.

Actions and Uses.—See Spleen (N. N. R., 1910, p. 144).

Dosage.—0.13 to 0.25 Gm. (2 to 4 grains) every three or four hours.

Manufactured by Armour & Co., Chicago. Not patented or trademarked.

Spleen Tablets-Armour.—Each tablet contains desiccated spleen 0.065 Gm. (1 grain).

Dose.—1 to 3 tablets three times a day.

DESICCATED PAROTID GLAND—Armour. — Desiccated Parotid Gland—Armour, consists of the fresh parotid gland of the ox, freed from fat, cleaned, dried and powdered, without the addition of either preservative or diluent.

A yellowish colored powder, having a slight peculiar odor. Partially soluble in water.

One part represents approximately 5 parts of the fresh parotid gland of the ox. Upon incineration, it should yield not more than 7 per cent. ash.

Actions and Uses.—See Parotid Gland. (N. N. R., 1910, p. 142).

Dosage.—0.2 to 0.3 Gm. (3 to 5 grains) three times daily.

Manufactured by Armour & Co., Chicago. Not patented or trademarked.

Parotid Tablets-Armour.—Each tablet contains desiccated parotid gland 0.13 Gm. (2 grains).

Dose.—1 to 2 tablets three times a day.

OVARIAN SUBSTANCE—Armour. — Ovarian Substance—Armour, consists of the entire fresh ovaries (including the corpora lutea) of the hog, cleaned, dried and powdered, without the addition of either preservative or diluent.

A yellowish colored powder having a peculiar odor. Partially soluble in water

One part represents approximately 6¾ parts of the fresh ovary of the hog. It contains gelatin, mucin, nuclein and the active constituent of the corpus luteum. Upon incineration, it should not yield more than 7 per cent. ash.

Actions and Uses.—See Ovary (N. N. R., 1910, p. 141).

Dosage.—0.06 to 0.2 Gm. (1 to 3 grains) three times daily.

Manufactured by Armour & Co., Chicago. Not patented or copyrighted.

Ovarian Substance Tablets-Armour.—Each tablet contains ovarian substance 0.13 Gm. (2 grains).

Dose.—1 to 2 tablets three times a day.

ORCHIC SUBSTANCE—Armour. — Orchic Substance—Armour, consists of the pulp from fresh ram testicles removed, dried and powdered, without the addition of preservative or diluent.

A light yellow powder, having a peculiar odor. Partly soluble in water.

One part represents approximately 7 parts of the fresh pulp from the ram testicle. Upon incineration, it should yield not more than 10 per cent. ash.

Actions and Uses.—See Testicle (N. N. R., 1910, p. 144).

Dosage.—0.13 to 0.3 Gm. (2 to 5 grains) three times a day.

Manufactured by Armour & Co., Chicago. Not patented or copyrighted.

Orchic Substance Tablets-Armour.—Each tablet contains orchic substance 0.13 Gm. (2 grains).

Dose.—1 to 3 tablets three times a day.

(*To be continued*)

Therapeutics

RHEUMATIC FEVER

This acute disease, that is in all probability an acute infection, is so serious for the future of the individual who is unfortunate enough to have an attack, that the repeated discussion of its treatment is always in order. In spite of a pretty good understanding of its management and of the frequency of its complications, its successful treatment as to shortening the duration and preventing cardiac complications has hardly advanced at all in many years. An article by Dr. Frank S. Meara, in the *American Journal of the Medical Sciences,* March, 1910, presents modern ideas of the best management of acute inflammatory rheumatism.

Meara recalls to our minds that about one-half of all cases of rheumatism occur between the ages of 15 and 25 and about one-quarter between 25 and 35. He is right in believing that there are many undiagnosed attacks of rheumatism in young children, as many times a child may have rheumatic fever without swelling, heat, or redness in the joints. It is possible that many unexplained valvular lesions of the heart, discovered in later years and attributed to various other infections such as scarlet fever or diphtheria, may really date from an undiagnosed rheumatism. On the other hand, infants who are generally babies who are fed on other food than mothers' milk, are many times believed to have rheumatism. (On the other hand, infants, who are generally babies who are fed on other food than mothers' milk, are many times believed to have rheumatism) when scurvy is the trouble. Children from 3 years upward should be carefully examined for slight fever, for some joint localization, and for cardiac disturbances if they have been or are subject to what has long been termed "growing pains." It should be remembered that a so-called subacute arthritis can allow or cause endocarditis with subsequent valvular lesions. Hence anyone with an arthritis, with much fever or with little, should be placed at rest, unless the joint inflammation is considered a surgical process and the joint is surgically immobilized.

A patient with acute rheumatism should have as much fresh, pure air in his bedroom as is now believed necessary in all the acute infections. Dampness and stagnant air are especially prone to perpetuate the disease while sunlight is a distinct aid in shortening the duration of the attack of rheumatic fever.

Meara believes that many acutely ill patients, and perhaps especially rheumatic patients, are under-fed, and he presents strong arguments for the administration of more food. A patient with fever certainly uses more calories of food than a patient without fever under the same conditions of rest, and it should be carefully decided how much and what kind of food he needs to obtain these necessary calories. He estimates that a man weighing about 150 pounds gives off at rest 2,300 calories, while the same patient with fever, such as rheumatic fever, will give off perhaps, 2,900 calories. A patient who is put on a rigid milk diet of about two quarts a day would take in not far from 1,200 calories, or not nearly what he is giving off. Consequently, he must burn his own fat and later his other tissues, this to his immediate direct disadvantage, and later perhaps, to his positive injury. It is theoretically absurd and clinically wrong to expect or cause a patient to drink enough milk to satisfy the need for calories or heat units (a calorie is considered to represent the heat that is required to raise one kilogram of water from 0 to 1° C.); it is therefore advisable that to the amount of milk, whether a quart, three pints, or two quarts, that is deemed suitable for the individual patient, should be added either cream, or starch, or sugar to furnish more calories for the needs of the body. Meara suggests adding considerable milk sugar to the milk, as furnishing many calories and not rendering it as sweet as cane sugar. Cereal gruels, as well represented by thoroughly cooked oatmeal gruel, will furnish a large number of calories, and makes a pleasant and nutritious food. Meara estimates that each of the following furnish 100 calories, viz.: "An ordinary thick slice of white bread (1⅓ ounces); an average ball of butter (about ½ an ounce); an ordinary helping of boiled rice (4 ounces); a large serving of oatmeal or hominy; 1½ ounces of cream; and 3 teaspoonfuls of granulated sugar."

As the wave of under-feeding has gone all over the country with such intensity that most patients who are seriously ill are under-fed, it is with pleasure that we present these suggestions for a better feeding of the rheumatic patient. Although we do not understand the part that extra acidity may or may not play in rheumatism, it certainly seems unwise to give such patients meat or meat protein foods, but the above diet as suggested is certainly a wise one. If there is much indigestion from the extra amount of fats and starches present, and as it is known that two elements are at work to reduce the normal gastric acidity, *viz.*, the extra amount of fat and milk and the fever, it can do no harm to administer, after the milk foods, a few drops of dilute hydrochloric acid 3 or 4 times in 24 hours. Whether the infection generally enters the system through the tonsils or more frequently through the intestinal tract, has not been determined, but certain it is that the less indigestion the less irritants are absorbed into the blood, the less the temperature, the less headache, restlessness, sleeplessness, and kidney irritation. There is nothing in rheumatic fever that should prevent the patient from having toasted bread, with butter, if desired, more or less frequently, portions of oranges, lemonade, and some salt with his milk or cereals. It should also be remembered that a patient who is on a diet that contains no iron should certainly receive a daily small dose of it, as represented by one or two drops of the official tincture of iron, or by 0.10 to 0.20 gram (1½ to 3 grains) of reduced iron, sugar of iron, or carbonate of iron.

Especially important in many diseases, but we believe paramount in rheumatic fever, the bowels should be kept in perfect active condition. When the patient is first seen, he should be thoroughly purged with some cathartic; whether salts, calomel, or castor oil should be determined by the individual choice of the physician and the age of the patient. Even if the patient is eating but little food, there is, as Meara emphasizes, a normal excretion from the bowels. The lower intestine should certainly be considered as an excretory organ, and even the washing out of mucous secretion and watery and toxic exudates must benefit any patient. The laxative which shall be used after the first purging must be determined by individualizing; possibly many times an enema will be sufficient, but certainly thorough evacuation of the bowels always reduces the temperature and relieves the patient of secondary toxemia. However, as Meara well cautions, frequent catharsis with salines or other active drugs is inadvisable. Laxatives, such as typically represented by cascara or by aloin in some good combination, and enemas are better than frequent saline purging.

The specific treatment of this disease seems to be clinically proved to be salicylic acid in some form, and Meara believes that too little is often administered, and he consequently gives to an "adult of average weight 20 grains, in one or other form, every 2 hours for the first 24 hours during the waking period, or even 48 hours. In severe cases even 30 grains may be given for the first 2 or 3 doses. When the pain subsides, the dose may be cut down gradually to 15, to 10, or to 5 grains at a dose, how much and how rapidly depending on the progress of events or the signs of accumulation. The dose should be well-maintained at amounts of 10 grains every 2 hours until the active phases, as evidenced by fever, pain, and joint swelling, have passed." He then gives his patients from "5 to 10 grains, every 2 or 3 hours for a week or 10 days after the subsidence of acute symptoms, and from 4 to 6 weeks a lesser dose of 5 grains 3 or 4 times a day." Salicylism, *viz.*, roaring or singing in the ears even to deafness, full-headedness, dizziness, gastric disturbances, and perhaps skin eruptions, urticarial or erythematous in type, he does not consider of enough importance, ordinarily, to stop the use of the drug. Albuminuria and hematuria he thinks can be caused by the disease as well as possibly by the salicylates.

These doses seem large, and theoretically it would seem that if a patient were saturated with the drug enough for the above symptoms, that the amount given might be reduced to just enough not to cause these symptoms. If, as he suggests, salicylic acid combats the germ of rheumatic fever as quinin does the germ of malaria, it might be best to give the salicylate in a large overwhelming dose once, perhaps, every 24 hours, preventing the head disturbance with bromids, in the same manner as quinin is best administered in malarial fever. It should be emphasized that when large doses of salicylic acid or sodium salicylate are administered, synthetic preparations should not be used. Salol, phenyl salicylate, should never be pushed in any such method as suggested, as it carries with it a phenol element that is toxic.

Meara does not state, but it is quite possible that part of the great good accomplished by salicylates is due to the fact that they cause a great amount of perspiration and therefore a large elimination by the skin of possibly the products of the disease. This can sometimes be accomplished perfectly by other methods. The writer of this editorial has frequently seen acute rheumatism almost aborted and certainly shortened by a general "body-bake," the hot-air treatment. Certainly, whenever it is possible, the body bake presents a most satisfactory treatment of rheumatism. Whatever the treatment, the frequent sponging of the body with hot water to remove the profuse, sour perspiration and the salts and toxins excreted by the skin, is physiologic as well as esthetic. Such sponging should be done at least twice a day.

Whatever the treatment, a patient who is in pain from rheumatism has a right to have it stopped, and a small amount of morphin is better than a large amount of a coal-tar product. This is always true when pain is constantly recurrent. The repeated administration of any coal-tar preparation is inadvisable in acute conditions. It is often not necessary to give large doses of morphin, and as Meara suggests, ⅛ or even 1/16 gr., hypodermatically, conjointly with the administration of salicylic acid will often give relief. This should be repeated, when the pain is severe, as often as it is needed. As Meara says, the value of potassium iodid and colchicum in acute rheumatism is probably mythical.

Whether alkalies are of much value or not is still undecided. Such treatment has its believers and disbelievers. A little extra alkali administered at such times (especially if antacid) as not to interfere with digestion can do no harm and may do considerable good. Meara suggests bicarbonate of sodium in amount sufficient to cause the urine to become alkaline. Potassium citrate would seem to be the better drug, as rendering the urine more quickly alkaline and causing less disturbance of the stomach and digestion.

The care of the individual joints which are inflamed cannot be dogmatically dictated. The joint and limb should be placed in the position that gives the patient the most comfort. If several joints of a limb are involved, and especially if there tends to be more or less troublesome muscle contractions, or an inadvertent movement causes excruciating pain, a splint may be devised to keep the limb at rest. Whether cold applications or warm applications are the best for other joints, depends on the feelings of the patient. Too continuous cold is perhaps best not applied, as tending so to deteriorate the circulation of the part as possibly to do harm. Generally, warm, moist applications, and perhaps nothing better than alcohol fomentations (one part of alcohol to 3 or 4 parts of warm water; a towel or napkin soaked in this and then wrung out just sufficiently not to drip, and this wound around the joint and then covered with oil silk) will probably give as much comfort as any application. These should be changed as frequently as they are cold. Sometimes dry cotton around the joint causes as much comfort as any application. The official methyl salicylate may be applied, or oil of wintergreen, but probably neither is more valuable than the above alcohol dressing.

Later when the acute inflammation in the joint has subsided, but the inflammation tends to persist in certain joints, ichthyol applications are much used and seem at times to be efficient in hastening the absorption of exudates. Ichthyol may be used in from 10 to 25 per cent. mixture with glycerin, or with olive or other bland oil. When there is acute rheumatic inflammation in the joint, counterirritation is contraindicated, but when a subacute inflammation persists, either fly blisters or the actual cautery are certainly advisable, and as Meara says, the cautery is generally the best treatment and is best applied in striæ around and over the joint, not cauterizing deeply enough to blister, and repeated once in 3 or 4 days. To prevent ankylosis or stiffening of joints that have been immobilized once every 5 days, they should be removed from the splints and slight motion made, when such motion is not severely painful.

If cardiac inflammation occurs and if the heart's action is impaired as shown by irregularity or increased rapidity of the heart beat, Meara believes, as is the consensus of opinion, that salicylates should be stopped. If there is no disturbance of the heart beat Meara does not believe that inflammation of it, though positively evident from auscultation, necessarily contraindicates the use of salicylates.

Anemia which so often follows rheumatism is perhaps frequently due to abstinence from meat and the prolonged administration of salicylates and alkalies. The constant administration of iron throughout the disease and a not too long use of salicylates and alkalies will generally prevent this condition.

The convalescence following rheumatism should be prolonged until the patient is thoroughly able to attend to his work. If there is a cardiac complication, such a recommendation is positively necessary. It can never be determined how much endocardial inflammation was present, how much valvular inflammation and thickening will be permanent, or how perfect the repair of the heart may be. Also, even when auscultatory evidence of cardiac complication has not been discovered, there may have been some inflammation which should call for prolonged rest. The administration of small doses of an iodid, best sodium iodid, from 0.10 to 0.20 gram (from 1½ to 3 grains) three times a day, is often advisable. Such treatment has frequently seemed to hasten or aid in the complete recovery of endocarditis. Not every endocarditis from rheumatism leaves valvular lesions.

Meat does not cause rheumatism, and prolonged abstinence from meat is generally inadvisable, still but a small amount of purin foods should be taken for some time. Eggs, green vegetables, and cereals should constitute the main food; later, fish or meat once a day may be allowed.

It has been urged, to prevent recurrences of rheumatism in those who have had it, that a week of salicylic acid treatment should be given once a month for a few months and then once in six months for several times. General prophylaxis is accomplished by the same old story now so constantly preached, and referred to by Meara. There should be plenty of warm water bathing; people should not sleep in ill-ventilated, damp, musty rooms; the bed clothing should be daily aired. Such clothing should be worn as is suitable for the climate, season of the year, environment and occupation. Overweighting of the body with unnecessary clothing, causing profuse, sticky perspiration that remains as a wet poultice over the body, will not only not prevent rheumatism, but may even be a promoting cause of it, and as Meara states, "sore throats, stiff necks, and 'growing pains' in children" should not be neglected.

ROBERT KOCH AND HIS ACHIEVEMENTS

Robert Koch, once a country doctor, the discoverer of the bacillus of tuberculosis, and with the immortal Pasteur, the founder of bacteriology, and of the germ theory of infectious diseases, died May 27, 1910. In what better way can we honor the memory of this preeminent man and benefactor of the human race, at this time and in this place, than by recalling, even if only in an incomplete and fragmentary fashion, some of the principal results of his life and work so that we may realize more fully than perhaps is the case in general what the world owes to him!

Koch was born Dec. 11, 1843, in Klausthal, Prussia. In 1862, having finished the gymnasium, he began the study of medicine in the University of Göttingen. On the faculty at that time were Friedrich Woehler, who first produced uric acid synthetically; the physiologist, Wagner, who discovered the germinal area in the ovum; and Jacob Henle, the great anatomist, who strove to unify anatomy, pathology and physiology, and who made important discoveries in microscopic anatomy. It has been suggested that probably Henle especially influenced Koch, because he was one of the first who advanced the idea that "contagium" is endowed with individual life and reproduces itself, growing by assimilation of organic material as it lives parasitically in the diseased body; he held that the as yet unseen parasites would be found to be vegetable in their nature.

While still a student Koch published the results of two investigations, one concerning the presence of ganglion cells in the nerves of the uterus, and another dealing with the question of the development of succinic acid in the animal body. In 1866 he received the degree of Doctor of Medicine, passed the state examination, and was now for a short time assistant physician in the general hospital at Hamburg; then he entered general practice in Langenhagen in Hanover. At this time he seriously considered the question of coming to this country, where two of his brothers had already established themselves, and of taking up the practice of medicine in St. Louis. He soon moved to a small place, Rackwitz, in Posen, and in 1872 he became *Kreisphysikus* or district physician in Wollstein, where he remained until he was called to the Imperial Board of Health in Berlin, in 1880. During this time he was a busy country doctor, and yet he, the unknown man, was now carrying on investigations on anthrax and on traumatic infective diseases the results of which at once placed him in the front rank of investigators and made him a leader in the new science of bacteriology.

BACTERIOLOGY BEFORE KOCH AND THE EFFECT OF HIS FIRST EXPERIMENTS

In order to understand clearly Koch's rôle in the development of bacteriology, it is necessary to cast a glance at the state of the knowledge of the relation of microbes to disease as it was in the early seventies. It is true that Pasteur had shown that spontaneous generation was a chimera and had published epochal researches which, through Lister, gave us the life-saving boon of antiseptic treatment of wounds; and yet the road had not been wholly opened which bacteriologic investigation was to take in the near future, the road which has led to the modern discoveries in the causation of infectious diseases, their treatment and prevention. In this then virgin field Koch did pioneer service and cultivated it fruitfully to the end. At the time in question the connection between bacteria and infectious diseases seemed on the whole obscure and uncertain. There was no lack of advocates of the germ theory of infection; the great Billroth was trying ably to establish his *Coccobacteria septica* as the cause of wound infections; and Klebs had described his *Microsporon septicum* in purulent septic wounds, and introduced his fractional method of cultivation, but the actual cause of any of these conditions had not been established in a wholly satisfactory manner. The question whether the bacteria found in certain diseases were the cause of the disease or merely a consequence had not been settled. Many apparently contradictory results were being recorded and it is no wonder that doubt would arise in the minds of many as to the value of the germ theory of disease, when we consider that the results of some investigators indicated that the same disease might be caused by different bacteria and that the same bacteria might cause different diseases. Nägeli taught that the same bacterium was capable of existing in numerous forms with different functional powers, and as late as 1877 he wrote: "I have for ten years examined thousands of different forms of bacteria, and I have not yet seen any absolute necessity for dividing them even into two distinct species." No final solution of the difficulties in the way of further progress was offered until Koch appeared and supplied the methods and indicated the experiments that were necessary to furnish a thoroughly satisfactory proof of the parasitic nature of an infectious disease.

In 1876 he published his work on anthrax. Pollender and others had found rods in the blood of animals with anthrax, and the disease had been produced experimentally by inoculation with blood containing such rods; but it was still, at least in some places, a disputed question whether the rods were living things or not and whether they were the cause of the disease. Koch settled the first question by observing directly under the microscope in a hollow ground slide that if a trace of infected blood was mixed with broth, the rods in it would develop into long threads which under certain conditions would break up into minute glistening round bodies that in turn would give rise to rods like those originally found in the blood. By actual experiment, he showed conclusively that the rods as well as the rounded bodies, both of which he interpreted to be stages in the development of a single micro-organism, could cause anthrax. It is narrated that at this point Koch went to Breslau, bringing with him his microscope and white mice, for the purpose of repeating the experiments in the presence of Ferdinand Cohn, the botanist, Cohnheim, Weigert and others. The demonstration made a profound impression. Cohnheim is said to have told the workers in his laboratory:

“Let everything stand as it is and go over to Koch; this man has made a great discovery which in its simplicity and exactness of method deserves only the more admiration because he is cut off from all scientific connections and has himself worked out everything to absolute completion. There is nothing at all more to do. I regard this as a great discovery in the field of micro-organisms and I believe that Koch will surprise and outdistance us all again with further discoveries.”

Robert Koch, 1843—1910

Two years later appeared the classical investigations on traumatic infective diseases, in which Koch showed conclusively by cultivation in the body of animals that there are specific, pathogenic bacteria which cause sharply defined transferable diseases; that pathogenic power is not a general or common characteristic of bacteria, of which there are many kinds, which have distinctive peculiarities; that bacteria of even similar form may differ widely in biologic properties. The appearance of this work marks the definite beginning of the era of exact bacteriologic-etiologic investigation.

Having solved the general question whether bacteria produce disease, Koch now made special preparations for the search for the special bacteria of individual diseases. He unremittingly attempted to improve the means “for the discovery of pathogenic bacteria in animal tissues, because he could not get rid of the idea that the doubtful results of investigations with regard to the parasites of infectious diseases might have their foundation in the incompleteness of the methods used.” He greatly advanced the technic, especially by the introduction of Abbé's condenser, by the use of the homogeneous oil immersion lens and of the recently introduced anilin dyes for staining.

In 1879 Koch was called to Breslau as *Gerichtsarzt*, but evidently this work did not suit him, as he soon returned to Wollstein, remaining here only a few months, however, before he was called to the Imperial Board of Health in Berlin in 1880. Loeffler, who was Koch's first assistant in Berlin, gives the credit of having fully recognized Koch's genius and of giving it opportunity for full development to Struck, the first director of the board of health. Koch, with Loeffler and Gaffky as assistants, began his work in Berlin, in a small room with one window, but before long they moved into a larger room with three windows. The investigations on anthrax were continued; photomicrography and new cultural methods were developed; the current teachings in regard to disinfection were completely overturned, and new and improved methods for testing disinfectants were devised; corrosive sublimate and live steam as disinfectants were introduced. Now he also worked out the so-called plate method for obtaining pure cultures of bacteria from single organisms; by this simple method, which is one of the corner-stones of practical bacteriology, a ready and invaluable means was furnished for the isolation of a single bacterial species or strain from a mixture of many. When Koch demonstrated his transparent solid media and plate method at the Congress of Hygiene in London, in 1881, Pasteur exclaimed: “C'est un grand progrès”!

KOCH'S WORK ON TUBERCULOSIS

In the meantime Koch had begun his work on tuberculosis.

It may be noted that tuberculosis had long been regarded as an infectious disease; that Klencke in 1843 produced tuberculosis in rabbits by the injection of human tuberculous material into the veins; that Villemin a little later, by numerous systematic experiments, became the founder of the study of experimental tuberculosis; that Cohnheim and Salomonsen more recently, by inoculation of rabbits, in the anterior chamber of the eye, where they could follow the development of the tubercles step by step, had shown that various tuberculous substances contain the same infective material. Because of these results and because of his observations on anthrax and on wound infections, Koch had reached the firm conviction that tuberculosis also is a parasitic disease, and so he now proceeded with untiring patience and skill to search for the parasite. It soon became clear that the agent of tuberculosis differed from other bacteria and that different staining methods would be necessary to reveal its presence. Koch's own words give the best idea of the progress of the work:

> I commenced my investigations with materials in which the infectious agent surely would be present, as for instance, freshly developed gray tubercles in the lungs of animals which were killed three to four weeks after inoculation. Sections were made from lungs hardened in alcohol and examined with the best methods for the demonstration of bacteria. Gray tubercles were also crushed, spread out on cover-glasses, dried, and then examined for the presence of micro-organisms. All efforts to find bacteria or other micro-organisms in these preparations were without result. As it had been found in some of the earlier experiments that the addition of alkalies to the staining solutions in certain cases proved of special advantage in staining the bacteria deeply and differently from the surrounding tissue, this method was next used. Of the anilin dyes methylene blue permits the addition of the largest amount of alkali, and hence so much potassium hydrate was added to the watery solution of this dye as could be done without producing a precipitate. One cubic centimeter of a concentrated alcoholic methylene blue solution was mixed with 200 c.c. of distilled water and after repeated shaking 0.2 c.c. of potassium hydrate was added. When cover-glass preparations were treated for twenty-four hours with this staining solution, very fine rod-shaped forms were seen in the tuberculous material, which, as shown by further investigation, may multiply and form spores, and consequently belong to the same group of organisms as the anthrax bacillus. In sections it proved much more difficult to recognize these bacilli between the densely crowded nuclei and masses of detritus; consequently it was tried by the method of Weigert, who succeeded in staining anthrax bacilli in a different color from the surrounding tissue elements, to make the tubercle bacilli more distinctly visible by differential staining. This purpose was achieved by the use of a watery solution of vesuvin with which the blue stain cover-glass preparations and sections were treated until they appeared in a pure brown color to the naked eye. Microscopic examination now showed that only the previously blue-stained cell nuclei and their disintegration products had taken on the brown color, but that the tubercle bacilli retained a beautiful blue color, in consequence of which they were clearly differentiated from their surroundings, so that even in the densely crowded nuclear masses they were easily recognized. . . .
>
> The bacteria have a rod shape and consequently belong to the group of bacilli. They are very thin and from ¼ to ½ as long as the diameter of a red blood corpuscle, occasionally reaching a greater length up to the diameter of a corpuscle. They show in form and size striking similarity with the lepra bacilli. However, they differ from the latter in that they are a little more slender and appear pointed at the ends. And the lepra bacilli take the stain with Weigert's nuclear staining method, which the tubercle bacilli absolutely do not.

The next problem, to obtain the bacilli in pure culture, free from all the constituents of the diseased body, was brilliantly solved by the use of blood serum solidified at 65 to 70 C., on which the bacilli grew freely, and by the inoculations of animals to determine whether the pure cultures actually consisted of the tuberculosis parasite; he secured positive results in every instance.

The first announcement of this wonderful and epochal discovery was made March 24, 1882, in the Berlin Physiologic Society. The communication bore the title "On Tuberculosis." As Koch quietly, soberly and without apparent emotion presented the details of his discovery, everyone in the large audience felt the tremendous importance of the occasion; when he finished no one spoke and the session closed without discussion. In print this classical communication, which is one of the most important in the literature of medicine, occupies about two pages like these. The work they record will always excite special admiration because of the completeness of the proof that tuberculosis is caused by the bacillus which Koch found. Not a stone is missing in the great structure.

THE DISCOVERY OF THE COMMA BACILLUS

Continuation of work on tuberculosis was soon prevented because in 1883 Koch was sent to Egypt to study cholera, which threatened to invade Europe. As the Egyptian epidemic soon subsided, it became necessary to proceed to India, where he finally completed his discovery, in the characteristic choleraic intestinal contents, of the comma bacillus, which he brought home with him in pure culture. In the course of his studies of cholera he reached a clear notion of the mode of dissemination of this disease, which proved to be of the utmost importance in the development of practical preventive measures; he recognized that the patient is the principal source and carrier of the germs and that the secret of prevention of epidemics lies in prompt recognition of the first cases.

While in Egypt he made important observations on Egyptian conjunctivitis (Koch-Weeks bacillus) and on amebic dysentery. On his return in 1884, he received 100,000 marks from the German government. In 1885 he was appointed professor in the University of Berlin, and director of the newly established Hygienic Institute. Long before this time his laboratory was thronged with physicians from many countries, who wished to learn bacteriologic methods. The number of students now increased greatly and Koch's methods were carried to all parts of the world.

Of the work of the many assistants and pupils who have reached eminence and made great discoveries no mention even by name can be made at this time.

THE DISCOVERY OF TUBERCULIN

In the first communication on tuberculosis Koch pointed out that the multiplication of the bacillus is limited to the living body and that the spread of the disease is due to discharges from tuberculous persons and animals, especially cattle. Koch devoted years to the search for substances which would destroy the bacilli in the infected body, but in vain. He then sought to cure tuberculosis by means of substances derived from cultures of tubercle bacilli in glycerin broth, and in 1890, at the Tenth International Medical Congress in Berlin, he presented a communication concerning tuberculin ("old tuberculin"), which *created the greatest* excitement. Koch claimed for this substance that it was an excellent means of diagnosis of tuberculosis in animals as well as human beings, and that it also would prove to be, so he hoped, a means of cure in the early stages of tuberculosis. The expectations in regard to the curative power of tuberculin were carried beyond reason, not only by physicians, but by the general public, and when it was found that these expectations were not realized, there followed unjust condemnation not only of the remedy but of the discoverer himself. In 1896 Koch brought forward his "new tuberculin." Experience has now shown that Koch was right in his claim that tuberculin is a reliable diagnostic means and, according to the opinions of numerous conservative physicians, it also possesses, when properly administered, a definite *healing power in certain forms of* tuberculosis. In connection with the experiments on the immunizing action of tuberculin investigations were carried on in his institute on immunization with other substances, which eventually led to the marvelous discovery by Behring of diphtheria antitoxin and to the helpful work of Ehrlich on the principles of immunity.

INVESTIGATIONS ON RINDERPEST, SURRA, BUBONIC PLAGUE, ETC.

In 1891 Koch was appointed director of the newly founded Institute for Infectious Diseases in Berlin.

In 1896, he was asked to go to Africa to study rinderpest and, while he did not discover the cause of this disease, he did find a method by which the animals might be immunized, namely, by the injection of the bile of animals that have died from the disease. Now followed investigations by Koch and his assistants of bubonic plague in India, as well as in Africa; of surra, a tropical disease of cattle and horses caused by a trypanosome, which is transmitted by the much-feared tsetse fly; and of Texas fever, in which case he confirmed the discovery of Theobald Smith that the causative agent *(Piroplasma bovis)* is carried by a tick. Koch's sojourn in Africa led to highly important studies of malaria. The discovery that the malarial parasites develop in mosquitoes and are inoculated into human beings by their bite was made first by Ronald Ross; the independent investigations of Koch led to exactly the same results and filled certain gaps in the researches of Ross. Koch's discovery of the frequency of malarial infection in native children is most important, because of the light thus thrown on the source of tropical malarial diseases and on immunity in malaria. Koch also introduced a new idea of prevention of malaria in the tropics, namely, by the preventive administration of quinin to the people in malarial districts.

DISCOVERY OF THE LACK OF IDENTITY OF HUMAN AND BOVINE TUBERCULOSIS

During these years Koch continued, so far as possible, the work on tuberculosis, and in 1901 he announced that he had reached the conclusion that human and bovine tuberculosis were not identical. He had found that human tuberculosis, as a rule, could not be transmitted to cattle, which are highly susceptible to bovine tuberculosis, and that there existed noteworthy distinctions between the bacilli of the two forms of tuberculosis. He consequently urged the view that bovine tuberculosis plays a minor rôle in the development of tuberculosis in man and emphasized again, and strongly, that the chief danger to man is the human disease. This pronouncement roused a storm of opposition and led to extensive investigations. At present it seems as if his claim that the bacilli of human tuberculosis have but little infective power for cattle may be regarded as established; it also appears to be agreed that certain definite differences exist between the bacilli of bovine and human tuberculosis; but the difficult and much-discussed question in regard to the frequency of transmission of bovine tuberculosis to human beings still awaits a final answer. As the matter now stands it seems that tubercle bacilli of the bovine type may be found in human beings and probably oftener than Koch believed in 1901 to be the case; the comparatively small number of cases, however, in which such bacilli have been found, as well as the frequency of human tuberculosis in regions where bovine tuberculosis is absent, or where the infection of human beings from this source may be excluded, nevertheless appear to support Koch's conception of the dominating importance of infection from person to person in the spread of human tuberculosis.

PREVENTION OF TYPHOID FEVER AND OTHER DISEASES

Koch's studies on typhoid fever have led to a change in the conception of the mode of transmission and to new methods for its suppression. The key to this method is exact and early diagnosis in every case. Every person who shelters the bacillus is a source of danger to healthy persons in his environment and consequently he must be *placed under conditions that obviate this* danger. This is the same principle which Koch applied with such success to the prevention of cholera in Germany, which he recommended for the suppression of malaria and sleeping-sickness, and which he believed eventually would be applied to tuberculosis, syphilis and other infectious diseases.

In 1904 Koch studied various protozoan diseases in German East Africa, and in 1906 he visited the interior of Africa, for the purpose of studying sleeping-sickness and the prevention of its ravages. In 1905 he received the Nobel prize in medicine.

He was active almost to the end. In 1908 he visited the United States and took an active and effective part in the International Congress on Tuberculosis at Washington, especially in discussions and conferences concerning the relation of human and bovine tuberculosis, a problem on which he proposed to work on his return to Berlin.

THE WORLD'S DEBT TO KOCH

But death has claimed the master and the world has lost its leader in the struggle against infection. Endowed with a mind of the first order, and animated, beneath a quiet, impassive and meditative exterior, by a spirit of unceasing but wonderfully well-regulated activity, which drove him on as by an internal fire from achievement to achievement, he made his own age preeminent over all the ages that have gone before for advances in the exact knowledge of the causation and prevention of infectious diseases. Rarely, if ever, have so many discoveries of such decisive importance to mankind emanated from the activities of one person; yet he served with all humility of mind. He simply tried to do his duty, being, as he said, fortunate to find sometimes the gold among the gravel of the road which is open to everyone. When we consider the advancement medicine owes to Robert Koch and the endless and inestimable blessing which has come to mankind through his work and life, there comes an overpowering sense of admiration, reverence and gratitude.

THE AMERICAN MEDICAL ASSOCIATION CALLED A TRUST

"Trust" is a good word to juggle with nowadays, for to most people it conjures up visions of extortion, robbery and general oppression. When, therefore, any organization is to be attacked and there are no tangible charges to be preferred against it, it is dubbed a "trust" and by that very token is damned in the premises. In this manner the American Medical Association becomes the "doctors' trust" according to the "National League for Medical Freedom"—and other organizations with equally high-sounding and misleading names, fathered by the "patent medicine" interests. Not that the term originated with this widely advertised "league," although some fifteen or sixteen years ago the president of this "league" attacked the medical profession in a magazine article on "Medical Monopoly." The representatives and mouthpieces of the proprietary interests have long employed it; notably Strong through his two journals, the *National Druggist* and the *Medical Brief*, and Engelhard through his journals, the *Western Druggist* and the *Medical Standard*. As the proprietors of these publications are found among the *personnel* of the "league" it is natural that this latest "patent medicine" organization should have appropriated a figure of speech possessing such magnificent potentialities.

To the proprietary men the American Medical Association is a trust because, they allege, it has attempted to dictate to physicians what medicinal preparations they shall and shall not use; or to put it more baldly, because the fraudulency and worthlessness of various proprietary products have been made clear in The Journal. Others have accused the Association of being a trust because it has attempted to raise the standard of medical education and thereby to "control the output of medical students." But the reason advanced by the "league" is a brand-new one, invented, no doubt, in the hope that it will reach the public's heart through its most direct route—the purse. The American Medical Association is a trust, we are told, because it has established a schedule of prices by which all its members are bound. The president of the "league" is reported as saying:

> "The [American Medical] Association now fixes the prices charged by physicians in America."

More specifically the "league's" vice-president puts it:

> "The American Medical Association has secured the adoption of its scale of prices throughout the country. . . ."

To such a charge there is but one answer and that an all-sufficient one, *viz.*, that it is a falsehood and a stupid one at that. Every physician, and every layman who has ever investigated the matter, knows that as a matter of fact the American Medical Association has never even suggested that the "price" of medical service be "fixed," but on the contrary, has positively discouraged such a proposition. The recommendation in the Principles of Medical Ethics that individual physicians in any locality should adopt some general rules "relative to the minimum pecuniary acknowledgement from their patients," has been taken and an attempt made to read into it a meaning never intended and certainly never accepted. What the attitude of the Association is on this point is well set forth in the standard "Constitution and By-Laws for County Societies" prepared by a committee of the American Medical Association and recommended and very generally adopted by various county societies:

> "Sec. 3.—Agreements and schedules of fees shall not be made by this society. . . ."

And yet the falsehood is blazoned forth, with a prodigal disregard for the expense entailed, by means of display advertisements and "interviews," that the American Medical Association "fixes the price" of medical service. Of course, the "league" had to have some shibboleth and the accusation that the American Medical Association is a "trust" is an untruth that may be counted on to arouse the interest of the unthinking and to give a more or less plausible excuse for the "league's" existence. How absurdly mendacious the accusation is the medical profession already knows and the public will not be long in learning.

Again we say: The publicity which the "patent medicine" interests are giving to the American Medical Association through this "league" is welcomed. The more the people know about the Association and the work it is doing, the keener the investigation made of its methods and aims, the better it will be not only for the American Medical Association and the medical profession of the country, but also, more important than all, for the public itself.

POISONING BY SUBLIMATE TABLETS

The recent publication[1] in The Journal of reports of several instances of fatal poisoning from the introduction of bichlorid of mercury tablets into the vagina has aroused some discussion of the growing danger from the promiscuous sale and increasing use of these convenient antiseptic preparations. In this connection the recent review of the cases of sublimate poisoning which have occurred in the German Empire during the years 1897 to 1905,[2] will undoubtedly have much interest.

By official action all cases of poisoning with bichlorid of mercury since 1897 have been reported to the governmental health office, and from the reports submitted the above-mentioned review has been compiled. It will undoubtedly cause some surprise that in the entire German Empire there occurred during nine years but one hundred and one cases of poisoning with bichlorid of mercury dispensed in tablet form, and twenty-three from sublimate sold as the powder or crystals, and this, in spite of the known prevalence of suicide in that country. Of the one hundred and one instances of poisoning with bichlorid tablets, no less than ninety-two were attempts at suicide, the other nine being accidental poisonings; there was no instance of the use of mercury for the purpose of murder, nor is there any record of poisoning from the introduction of tablets into the vagina as has been mentioned above. The mortality was not so high as might have been anticipated, fifty-eight persons dying while forty-three recovered, in spite of the fact that most of these were cases of suicide, in which therapeutic intervention is not usually so prompt as in accidental poisoning. The greater inclination of women to commit suicide by poison rather than by more violent means is brought out by these tables, for in thirty-four cases in which the sex is recorded twenty-five women and but nine men used bichlorid of mercury with suicidal intent.

Compared with the tablets, bichlorid of mercury in the unmodified form is a rare source of serious poisoning, however often it may lead to slight local or constitutional symptoms in persons using it frequently. There were but twenty-three cases of poisoning by this form of mercury during the same nine years. Of these, sixteen were suicidal and six accidental, including under the latter two cases in which fatal poisoning followed injections of sublimate solution for the purpose of producing abortion. In any case it is evident that bichlorid of mercury as compared with compound solution of cresol, phenol, and even phosphorus, is not a popular poison for suicidal purposes in Germany. During the nine years under consideration there were reported in Prussia alone 2,895 suicides by poison, of which but thirty-six or 1.2 per cent. were from antiseptic tablets containing sublimate.

We have a distinct impression that poisoning by this agent, especially accidental poisoning, is much more frequent in this country than these figures show it to be in Germany; unfortunately there is no way of learning the exact conditions in America because of our laxity in the matter of vital statistics. There is every reason why we should have more poisonings by bichlorid tablets than the Germans have, for here almost anyone can secure a bottle of them at any time, and almost every household has a partly used bottle in some cupboard inviting mistaken administration by self-drugging adults, or accidental assimilation by inquisitive children. In Germany, however, it is not so easy to buy or unintentionally to poison oneself with bichlorid tablets, because of the enforcement of rigid laws regulating their sale. Among the legal provisions are the following: For medical purposes sublimate tablets can be sold only by apothecaries, and only on the presentation of a dated and signed order from a regular physician; each tablet must contain a soluble red anilin dye, and it must be enclosed separately in a black paper on which is printed the word "poison" in white letters, in addition to the usual regulations concerning the marking of the containers.

With such regulations in force it is easily understood why only one accidental poisoning occurs annually in Germany from this source, and that a suicidally inclined person will have some trouble in securing this particular means of escape from life's cares. As a matter of fact, a remarkably large proportion of those who did take bichlorid with suicidal intent were nurses, midwives, servants of doctors, and others who could procure the antiseptic tablets readily—a fact which shows how efficient the German laws are in keeping this particular poison from being improperly used by the general public. The conclusion reached by the official who investigated these statistics for the governmental health officers is that the existing regulations have proved themselves so efficient that there is no need for any further restriction being placed on the use and sale of bichlorid of mercury tablets, in view of their well-established usefulness. It is a pity that we have no available statistics in this country for a similar study; it is reasonably certain that the inevitable conclusion would be that in this country there is urgent need for the adoption and enforcement of regulations similar to those which have so effectively protected the German public.

Tefft Memorial Services.—Memorial services in honor of the late Dr. Jonathan E. Tefft were held by the Greene County Medical Society, at Springfield, May 13. A number of addresses were made and the medical library of Dr. Tefft was presented to the society by his widow.

Graduating Exercises.—At the graduating exercises of the University Medical College, Kansas City, held May 13, a class of forty-seven received diplomas. Rev. Cyrus Townsend Brady delivered the doctorate address and Dr. Jabez N. Jackson presented the diplomas and awarded the prizes.

Medical Secretaries Meet.—At the second annual meeting of the Missouri Society of Medical Secretaries, held in Hannibal, May 3, the following officers were elected: President, Dr. George W. Goins, Breckenridge; vice-presidents, Drs. Bert B. Parrish, Kirksville; Vincent O. Williams, Nevada, and secretary-treasurer, Dr. Charles Wood Fassett, St. Joseph. The next meeting of the society will be held in Jefferson City on May 11. Dr. Frederick R. Green, assistant secretary of the American Medical Association, was a guest of the society and delivered an address on "Medical Reorganization—Past and Present."

St. Louis

Personal.—Dr. John C. Morfit has been appointed first hospital commissioner under the new hospital commission.——Drs. Major G. Seelig, Willis B. Young and Harvey G. Mudd have been appointed members of the surgical visiting staff of the new St. Louis City Hospital, and Drs. George C. Crandall, Carl J. Luyties and Elsworth Smith, Jr., members of the visiting medical staff.

Commencement Exercises.—The commencement exercises of Barnes University Medical Department were held in St. Louis May 16. A class of fifty-one received diplomas from Dr. Alonzo R. Kieffer, dean of the faculty. The doctorate address was made by the Rev. W. M. Wilkinson and the honorary degree of Doctor of Medicine was conferred on David C. Morrow, secretary of the dental department.

Fraternity to Meet.—The second international meeting and dinner of the Alpha Omega Medical Scholarship Society will be held under the auspices of the Washington University Chapter at the St. Louis Club, 3663 Lindell Avenue, at 6:30 Tuesday evening, June 7. The tickets are $2 and members may bring friends. Announcement will be made at this meeting of the time and place of a special meeting of delegates to be held later.

MONTANA

Hospital Opened.—The Geiger Building, Libby, has been fitted up by Drs. E. F. Coyningham and Robert Auld. It will be known as the Libby General Hospital.

Personal.—Dr. Willard A. Long, Lewistown, with his wife and daughter, sails for Europe June 11. Dr. John T. Foley will act as health officer during the absence of Dr. Long.

State Board of Health Meeting.—At the annual meeting of the State Board of Health, held at Hunters Hot Springs, May 10, the following officers were elected: Dr. Samuel E. Leard, Livingston, president, and Dr. Thomas D. Tuttle, Helena, secretary.

NEBRASKA

Tuberculosis Camp Project Abandoned.—The opposition of property owners has resulted in the abandonment of the project to establish a tuberculosis hospital at Pries Lake, north of Florence.

County Medical Society Meeting.—Cuming County Medical Association at its annual meeting held in West Point, elected Dr. Harry W. Francis, Bancroft, president, and Dr. Harry L. Wells, West Point, secretary.

NEW YORK

Charities Aid Report.—The thirty-seventh annual report of the Charities Aid Association has just appeared. Legislation creating the Board of Ambulance Service for Greater New York was one of the reforms obtained by the association. The society also aided in the effort to obtain ambulance relief stations in three different sections of Greater New York. Two bills have become laws, one authorizing the establishment of county hospitals for tuberculosis, and the other providing for the ambulance service of New York City. They also drafted a bill providing for the more adequate treatment of intoxica- tion and inebriety in this city, but the bill failed of passage. Owing to the increase of the association's work for children there was a deficit of $2,500 in the general fund.

Heavy Cost of the Insane.—According to the statement issued by the state controller recently, the largest item of expenditure during the past ten years has been for the support of state hospitals for the insane. During the last decade this expenditure amounted to $54,018,361. The state lunacy commission reports that during the last year 6,474 patients were received into the state hospitals and 23 per cent. as many were discharged, recovered. The total number now under treatment is 31,000. Dr. Albert Warren Ferris, New York City, president of the state lunacy commission, read a paper at the annual meeting of the American Medico-Psychological Association urging certain preventive measures to be inaugurated immediately, as they would result in great saving to the state.

Buffalo

Section Officers Elected.—The section of medicine of the Buffalo Academy of Medicine has elected Dr. Lesser Kauffman, chairman, and Dr. Carl S. Tompkins, secretary.

Law Against Spiritualists and Clairvoyants.—As the result of the acquittal of Mrs. Lane, a spiritualist or clairvoyant, Erie County Medical Society has had drawn a bill for the purpose not only of stopping the practice of spiritualists and clairvoyants, but with the intent to put a stop to all mental healers who practice for money consideration. The bill provides that every person practicing the healing art must have a diploma. The bill has been passed by the general assembly.

Care of Insane Before Commitment.—The report of the committee appointed by the Buffalo Academy of Medicine on the care of the insane prior to commitment shows the need of improvement in the methods in vogue in the state. Although the best care should be taken of the insane, the fact still remains that more than 37 per cent. of the men and more than 10 per cent. of the women committed to the Buffalo State Hospital have been sent from jails and police stations. The committee found many instances of long delays and lack of considerate care, neglect and improper provision.

OHIO

Governor Refuses Optometrists.—In spite of the efforts of a committee of the Ohio Optical Association, headed by the vice-president, Governor Harmon has refused to reconsider his veto of the Dean Optometry Bill.

Personal.—Dr. Francis P. Corrigan, Cleveland, has returned from Europe.——Dr. Asa C. Messenger has been appointed health officer of Xenia.——Dr. Louis F. Bucher has been appointed medical inspector of the Board of Education of Dayton, and Dr. John W. McKenny has been appointed a member of the board.

College Commencement.—The third annual commencement exercises of Starling-Ohio Medical College, Columbus, were held May 18, when a class of 39 was graduated. President W. C. Thompson of the Ohio State University delivered an address and conferred the degrees and Oscar T. Corson, formerly State School Commissioner, delivered the commencement address.

Damages Against Physician.—In the case of Mrs. Sarah V. Palmer against Dr. William H. Humiston, Cleveland, in which it was alleged that, after a surgical operation, the defendant had allowed a gauze sponge to remain in the wound, which was removed six months later by another operation, a verdict of $5,000 damages is said to have been awarded the plaintiff, April 30.

School for National Guard Medical Officers.—A school for medical officers of the Ohio National Guard will be held in Columbus, June 8 and 9. The instructors, who are all of the Medical Corps of the Army, are Major Edward L. Munson, Fort Leavenworth; Major Charles R. Reynolds, Fortress Monroe; Major Henry C. Fisher, Columbus Barracks, and Capt. W. Henry Pipes, Washington, D. C.

Societies Meet.—The physicians of Salem met April 25 and organized the Salem Physicians' Club, with Dr. Andrew W. Schiller, president, and Dr. Paul E. Barckhoff, secretary.——At the meeting of the Ohio Alumni of Jefferson Medical College, held in Toledo, May 12, Dr. Albert W. Fisher, Toledo, was elected honorary president; Dr. Richard S. Gaugler, Dayton, president; Dr. Silas W. Fowler, Delaware, vice-president, and Dr. Fred Fletcher, Columbus, secretary and treasurer.

In the Hands of the Law.—Dr. John C. Snyder, Bowling Green, is said to have been convicted in the probate court of the illegal prescription of liquor to a detective named Collier, and to have been fined $250 and costs. However, $200 of the fine was suspended until further order of the court.——Dr. Jacob F. Wallom, Jerry City, charged on several counts of selling liquor in violation of the law, was discharged April 29. ——James M. Laburg, Miamisburg, whose certificate is said recently to have been revoked by the state medical board on the charge of unprofessional conduct has been granted a new trial by the governor and attorney-general sitting as a court of appeal.

Cincinnati

Personal.—Dr. Robert D. Mussey, receiving physician of *the City Hospital*, has resigned to accept a position in Rochester, Minn., and has been succeeded by Dr. Charles Howard.——Dr. J. C. Cadwallader, for fifteen years health officer of Norwood, has resigned and has been appointed chairman of the board of health; Dr. Frank Perry has been appointed health officer and Dr. Louis Sauer district physician.——Dr. Simon P. Kramer has sailed for Europe.——Drs. William E. Lewis, professor of anatomy, Charles L. Metz and Moses Salzer, demonstrators of anatomy, Grear Hill Baker, demonstrator of biology, Walter R. Griess, lecturer on applied anatomy, and Henry L. Woodward, demonstrator of embryology, have left the faculty of the Ohio-Miami Medical College. It is reported that a new head of the department from an eastern college is to be appointed who is expected to select his own staff.

OKLAHOMA

Protective Association Organized.—The Tilman County Physicians' Protective Association was organized at Frederick recently and the following officers were elected: Dr. Fred G. Priestly, president, and Dr. Adam B. Fair, secretary, both of Frederick.

OREGON

Commencement.—The Medical Department of the University of Oregon, at its annual commencement exercises, May 2, graduated a class of fifteen. Hon. Abbott Low Mills delivered the annual address, President P. L. Campbell conferred the degrees and presented the Saylor and anatomy medals, and Dr. Edmund J. Labbe delivered the charge to the graduating class.

New Hospitals.—Granite City Hospital, with a capacity of 50 patients, a new hospital of solid concrete construction, and which has cost about $40,000, was formally opened in Ashland, April 30.——Mrs. Millie Trumbell, Portland, is agitating actively the matter of an emergency hospital for Portland, to be located in the new Multnomah County Courthouse. She is also advocating the instruction of the police in first-aid to the injured.——Ground is reported to have been secured for the erection of a hospital for Chinese in Portland and $40,000 has been subscribed for the institution.

PENNSYLVANIA

Personal.—Dr. J. Budd Rees has resigned as resident physician at Pottstown Hospital.——Dr. Edward R. Myers has been elected president of the board of health of Pittston, and Dr. Edward F. McGinty a *member of the board*.

State to Care for Tubercular Children.—Announcement was made by Dr. Samuel G. Dixon, State Commissioner of Health, May 24, that a special department for tubercular children is being established at Mount Alto and that separate children's clinics will be held at the dispensary every Saturday from 1 to 4 p. m. Dr. Charles Weber, an expert on diseases of children, has been appointed to examine and look after these patients. Cases among children will be reported by the public school authorities, and the new children's building at Mount Alto will be utilized to take care of the more advanced cases.

Tuberculosis Notes.—Berks County Tuberculosis Sanatorium on Neversink Mountain, opened for the season, May 12, with accommodations for fifteen patients.——At a meeting held in Erie, May 13, a local branch of the state society for the prevention of tuberculosis was organized. Drs. John W. Wright, Edward Cranch and George B. Kalb were elected vice-presidents.——A contract has been awarded by the State Department of Health for the erection of a group of buildings conisting of a dining hall, infirmary, nurse's home, physician's ouse and ward building, at the State Sanatorium, Mount Alto, the cost of the buildings to be $106,000.——A contract as been awarded for the building of an addition to the Hometead Hospital, to be three stories in height, of brick, and to ost about $10,000.

Philadelphia

Gone to Europe.—The following physicians have sailed for Europe: Drs. J. Nicholas Mitchell, Alfred Bernstein, and Howard T. Karsner.

Bequests.—The will of the late John H. Converse bequeathes 25,000 to the Presbyterian Hospital.——By the will of the late Samuel E. Shoyer, the Jewish Hospital receives a bequest of $5,000 for the establishment of a free bed in memory of Gabriel and Louisa Shoyer.——The will of the late Lucinda Dodson devises $8,000 in trust for the benefit of Albert B. Dodson and at his death $5,000 is to be given to the Methodist Episcopal Hospital to endow one or more free beds.

Hospital Staff Appointed.—Dr. Joseph S. Neff, director of Health and Charities, appointed the following staff of visiting physicians at the Tuberculosis Hospital, Byberry: Drs. Ward Brinton, Samuel Rhoads, Arthur C. Morgan, Daniel M. Hoyt, Edward J. G. Beardsley, Joseph V. C. Roberts, J. Clinton Foltz, and J. Willoughby Irwin. The plan of the department is to receive from the various hospitals of the city, all those cases of consumption, among the deserving poor, that are moderately advanced—that is, those for whom there is the slightest hope of recovery—and there keep them under the direct care of visiting physicians. Dr. Henry Sykes, chief resident physician, has sent examining blanks to all the city hospitals and on May 27 10 patients were sent from the Philadelphia General Hospital and 6 from Jefferson Medical College Hospital.

Furthering the Baby-Saving Campaign.—To further the plans of last week for the baby-saving campaign this summer, another meeting was held at Dr. Neff's office at City Hall on May 20 and the following committee was appointed: Dr. Jesse D. Burks, director, Bureau of Municipal Research; Miss Lucy Davis, secretary, Visiting Nurse Society; Dr. Samuel McC. Hamill, Pediatric Society; Miss Anna Jeffries, superintendent, St. Christopher's Hospital for Children; J. Percy Keating, vice president, Society for Prevention of Cruelty to Children; Miss Mary V. Kemp, Church House Settlement; Porter R. Lee, general secretary, Society for Organizing Charity; the Rev. H. Cresson McHenry, assistant superintendent, Protestant Episcopal City Mission; J. Prentice Murphy, superintendent, Children's Bureau; Mrs Solomon Selig, Juvenile Aid Committee; Dr. Louis Starr, Mrs. E. Boyd Weitzel, president, Country Week Association. Mayor Reyburn forwarded a message to Councils asking that $5,400 be appropriated immediately toward the establishment of a Division of Child Hygiene, under the Department of Health and Charities. All through the 18 schools of the second, third, fourth, fifth, sixth and seventh wards, lectures under the joint supervision of the Bureau of Health, the Visiting Nurses and the Bureau of Municipal Research, were given by Dr. Neff's medical inspectors, assisted by the school nurses, May 26. These were simple practical talks to the little girls, on the care of babies, the proper way to dress them and most important of all—the care of their milk and bottles. It is hoped that these "little mothers," who practically have full charge of the babies of their families will carry out these precepts. The work which will center in the two downtown wards where the death rate among babies is highest, will begin June 1. Every house where a birth is reported or where a baby is known to live, will be visited and advice and instruction will be given to the mother. In order to facilitate prompt notification of births, Dr. Neff has planned to have reports of births sent informally by postcard or telephone within 24 hours to the Central Registration Bureau, instead of waiting for the allowed 10 days. In a house where there is no regular attending physician, the nurse will leave an addressed postal card, which can be used to notify the Health Department in case of the baby's illness. Upon receipt of such notification, the department will investigate through one of its physicians and the physician and nurse will render assistance as long as may be necessary.

VERMONT

Personal.—Dr. Everal C. Haviland, first assistant physician of Brattleboro Retreat, has resigned.——Dr. James D. Tanner, Burlington, sailed for Europe, April 23.——Dr. Clarence F. Ball has been reappointed health officer of Rutland.

State Board Meeting.—The State Board of Health in Rutland, May 12, decided to hold the summer school for health officers in Montpelier during the first week in August, and to discontinue, for the season, the tour of the tuberculosis exhibit.

VIRGINIA

Buildings for Epileptic Colony.—The board of trustees of the state epileptic colony of Amherst County near Lynchburg, expects to have its work well under way by September 1. The present three buildings on the farm will be utilized, one as a cottage for inmates, one as an administration building and a third for farm employees. Plans for a new building have been accepted and the building will be ready for occupancy by the end of the year.

GENERAL NEWS AND COMMENT

Medical Librarians' Meeting.—The Medical Library Association will hold its thirteenth annual meeting in the Southern Hotel, St. Louis, June 6 and 7, under the presidency of Dr. John H. Musser, Philadelphia. The association will discuss matters relative to libraries and library movements.

Gastroenterologists to Meet.—The thirteenth annual meeting of the American Gastroenterological Association will be held in St. Louis, June 6 and 7, at the Planter's Hotel, under the presidency of Dr. Julius Friedenwald, Baltimore, the subject of whose address will be "Recent Events in the Development of Gastroenterology."

Harvard Alumni to Meet at St. Louis.—Harvard alumni attending the American Medical Association meeting at St. Louis will meet at the University Club for dinner, at 6:30 p. m., June 7. Dr. John Green will act as toastmaster. There will be a desk for registration at the general headquarters in the Southern Hotel, where the Alumni are urged to register. Dr. Nathaniel Allison, 609 Metropolitan Building, is in charge of the arrangements.

Meeting of State Medical Examining Boards.—The twentieth annual convention of the National Confederation of State Medical Examining and Licensing Boards will be held in the Southern Hotel, St. Louis, June 6, under the presidency of Dr. Augustus Ravogli, Cincinnati, the subject of whose address is "A Plea for More Practical and Extended Clinical Instructions for Medical Students." The matter of combining the American and National confederations will come up for action before this meeting.

Frisco Surgeons Meet.—The ninth annual convention of the Frisco System Medical Association was held in Springfield, Mo., May 16 and 17. St. Louis was selected as the place of meeting for 1911 and the following officers were elected: President, Dr. Elijah J. Neathery, Sherman, Texas; vice-presidents, Drs. William S. McDonald, Fort Scott, Kan., and James R. Dawson, Birmingham, Ala.; secretary, Dr. Stanton K. Crawford, St. Louis (reelected); treasurer, Walter A. Camp, Springfield, Mo. (reelected), and Dr. William Britt Burns, Memphis, Tenn., member of the executive committee.

Conference Regarding Feeble-Minded.—The thirty-fourth annual conference of the American Association for the Study of the Feeble-Minded was held at the Lincoln (Ill.) State School and Colony, May 16 to 18. The following officers were elected: President, Dr. Arthur R. T. Wylie, Faribault, Minn., vice-president, Dr. Harry G. Hardt, Lincoln; secretary and treasurer and editor-in-chief of the *Journal of Psycho-Asthenics*, Dr. A. C. Rogers, Faribault, Minn., and associate editors, Drs. Walter E. Fernald, Waverly, Mass.; Martin W. Barr, Elwyn, Pa.; George Mogridge, Glenwood, Iowa; Arthur R. T. Wylie, Faribault, Minn.; H. H. Goddard, Vineland, N. J.; Harry G. Hardt, Lincoln, Ill., and Charles S. Little, Laconia, N. H.

Prevention of Infant Mortality.—At the annual meeting of the American Association for the Study and Prevention of Infant Mortality, to be held in Baltimore November 10 and 11, the session on Municipal, State and Federal Prevention will be in charge of Dr. Wm. H. Welch, Baltimore, chairman, and Dr. John S. Fulton, Washington, D. C., secretary; the session on Medical Prevention will be presided over by Dr. L. Emmett Holt, New York City, with Dr. Philip Van Ingen, New York City, as secretary; Dr. Helen C. Putnam, Providence, R. I., will preside over the session on Educational Prevention and Prof. Abby Marlatt of the University of Wisconsin will be secretary, and Hastings H. Hart, New York City, will be in charge of the session on Philanthropic Prevention.

LONDON LETTER

(From Our Regular Correspondent)

London, May 14, 1910.

The Death of King Edward

The death of the King, after a brief illness, on May 6, in his sixty-ninth year, has fallen as a heavy blow on all his subjects throughout his vast empire. We realize that we have lost a ruler of exceptional merits whose one idea was the service of his people by the promotion of peace among nations. With what skill he worked for this ideal and attained a title which has never been borne before, "the world's peacemaker," is well-known. His success depended not on intellectual greatness but on a personality of singular charm. He has been well described as "The kindest man who ever wore a crown." He always took a great interest in the profession of medicine and he was a staunch friend of it. In collecting funds for the hospitals he was foremost. He founded the "King Edward's Hospital Fund" from which large grants are made every year to all the London hospitals. In the scientific aspects of medicine he was also deeply interested. As Prince of Wales he presided at the last International Medical Congress held in London and his interest in the problems of tuberculosis and cancer are well-known. In the anti-tuberculosis campaign he made the epigrammatic remark which has often been quoted: "If preventable why not prevented." Speaking of cancer investigation he said that the man who discovered a cure for that dire disease deserved to have a statue erected to his memory in all the capitals of the world.

The Treatment of Cancer

The practice of the Cancer Hospital, London, is of interest as showing the results of the latest methods of treating cancer. The electrical department is well-equipped with apparatus for the *x*-rays, ionic medication, high-frequency currents and radium therapy. Last year nearly 2,000 treatments were administered. As before, the *x*-rays have been found to alleviate a considerable number of cases but no cures can be claimed. The use of the high-frequency currents is limited to the relief of pain. Ionic medication has given good results in some cases but it has failed in extensive, inoperable and internal cancer. At a cost of $1,000 20 milligrammes of radium have been obtained. In superficial cancer radium has given good results and certain cases can be claimed as cured. But in the deep-seated cases of advanced growth all that has been obtained is temporary checking of the disease and relief of pain. The trypsin treatment for which so much was claimed has proved a complete failure. The same is true for the serum of Doyen of Paris. In spite of these results, however, the fact that in rare cases (estimated to be somewhat less than 1 in 1,000) cancer undergoes spontaneous cure, that in others the natural resistance of the body to the growth of cancer is great, and that Nature by means of fibrosis and sloughing attempts to get rid of the disease seem to give hope of the discovery of a cure, and point to a serum treatment. At present another serum treatment is being tried.

Disappearance of Yellow Fever from the West Indies

Prof. Rupert Boyce, who has just returned from Jamaica, reports that the old-time scourge of the West Indies has practically disappeared. About the year 1850 the introduction of water-pipes in nearly all the principal towns did away with the necessity for wells, vats and barrels, the breeding-places of the stegomyia, greatly reducing its numbers and the number of cases of yellow fever. Professor Boyce states that whenever an appreciable, though not necessarily a complete reduction in the number of stegomyia, is brought about in a district, from that time yellow fever ceases to be endemic. In short, a certain excess of this mosquito appears necessary to maintain continuous infection or endemicity; short of that number endemicity disappears. But if by chance a case of yellow fever should be imported from some distant center in Central America, where the disease is still endemic, then a smaller or larger outbreak will occur, limited in extent by the number of stegomyia existing in the particular district. These outbreaks, despite increasing commercial relations, are every year becoming less frequent and smaller.

PARIS LETTER

(From Our Regular Correspondent)

Paris, May 13, 1910.

Physicians in the Chamber of Deputies

The new Chamber of Deputies, elected on April 24 and May 8, comprises 597 deputies, among whom are 49 physicians. In the former chamber there were only 591 deputies, of whom 54 were physicians. This proportion appears larger, because the other professions, except those of law and journalism, are represented by much smaller numbers. Among the new deputies there are only 13 pharmacists. There are, however, about 120 lawyers. A well-known publicist, M. Henry Maret, who never fails to disparage physicians a little, asks why there are so many lawyers and physicians, and goes on to say that it is easy to understand why there are so many lawyers; it is their business to understand the law and it is natural for them to be called on to make laws; but, he asks, what relation has the medical profession with the conduct of the governmental affairs? Literature, it has been wittily said, leads to everything, provided one forsakes it. "Just as good writers keep out of politics," M. Maret remarks, "the best physicians are not those who become legislators."

There may be some truth in this observation; but medicine and social hygiene are called on to play an important rôle in modern legislation. The medical profession, moreover, h furnished some eminent men to politics. Two former premiers, who played a considerable rôle in recent years, M. Combes and M. Clemenceau, were medical men. One of the most prominent members of the last legislature, M. Fernand Dubief, former vice-president of the Chamber of Deputies, who has twice been a minister, is likewise a physician, and consequently took an active part in legislation requiring special knowledge along this line, such as the laws on industrial accidents and reform of legislation in regard to the insane, etc.

The Jubilee of Dr. Gellé Père

In one of my previous letters (THE JOURNAL, March 26, 1910, liv, 1069) I mentioned the formation of a committee to take charge of the celebration of the jubilee of Dr. M. E. Gellé. This ceremony took place, under the presidency of Dr. F. Raymond, professor at the Paris college of medicine, and many otologists were present, colleagues, pupils and friends of Dr. Gellé. Letters of congratulation were read from Austrian, Belgian, Spanish, Italian, Dutch and Roumanian otologic societies. At the close of the ceremony, Dr. Gellé was presented with an artistic medal, bearing his own portrait, the work of A. Boucher.

A Victim of Medical Duty

M. Neyraud, intern under Dr. Donnet, professor of clinical obstetrics in the Limoges medical school, has just died of septicemia, due to a scratch infected by the pus from a salpingitis on which an operation had been done. The administration of the Limoges hospital has undertaken to defray the expense of Neyraud's funeral and to pay suitable honors to his remains. The minister of public instruction has ordered academic palms to be placed on the coffin of the young victim of professional duty.

Death of Professor Trolard

The death is reported of Dr. Paulin Trolard, professor of anatomy in the Algiers college of medicine. Dr. Trolard had been since 1906 a national correspondent of the Académie de Médecine.

Treatment of Wounds of the Hands with Tincture of Iodin

During the session, May 3, of the Académie de Médecine, Dr. Paul Reclus, professor of clinical surgery at the Paris college of medicine, made a report on the treatment of wounds of the hands by painting with tincture of iodin. The treatment of such wounds has taken on much importance since the passage of the law on industrial accidents. It is well known how wide-spread is the practice of washing the hands of wounded workmen with benzin, gasoline or ether before treating them. This practice ordinarily results in the infection of the wound by the diffusion and dissemination of the microbes, which multiply in the dust deposited in the folds and wrinkles of the skin of the fingers. Dr. Paul Reclus believes that no preliminary disinfection should be done and that immediately after the accident the wounded region should be painted with tincture of iodin, a layer of which should be deposited all around and over the wound itself. When the tincture of iodin has once evaporated the region should be covered by an aseptic compress and a pad of absorbent wadding held in place by a bandage. This painting, which should be renewed every day, insures perfect asepsis of the wound, reduces inflammation to the minimum and leads to rapid cure. In order to avoid blistering, only a freshly prepared tincture of iodin should be used. On account of its extreme simplicity, dressing with tincture of iodin is capable of rendering great service in all urgent cases and especially in times of war.

BERLIN LETTER

(From Our Regular Correspondent)

BERLIN, May 13, 1910.

Personals

Professor Curschmann of Leipsic, director of the medical clinic at that place, died May 6 at the age of 63. His death was unexpected, especially by those who, like myself, had the opportunity to see him at the meeting of the association for internal medicine in full bodily and mental vigor. Influenza of a few days' standing attacked his heart and suddenly terminated his life. In Curschmann there has departed from us a great investigator, teacher and physician. He entered on his teaching career in 1875 at the university of Berlin and in the same year was appointed at the age of 29 as chief physician at the Moabit hospital. As a result of the success which he achieved in this position he was called in 1879 to Hamburg as the director of the state hospital. Here he directed the building of the new general hospital at Eppendorff and showed a remarkable knowledge of hospital building and hospital management, so that the hospital under his direction was for a long time recognized as the model hospital of Germany. In 1888 he was called to Leipsic as the successor of the renowned clinician Wagner and in this position, in spite of numerous invitations from other universities, he remained until his death. Curschmann produced a long series of scientific articles and works. Of his monographs, his article on typhoid fever in Nothnagel's treatise is especially notable. All his articles bear the stamp of wide experience and thorough criticism; they are clearly written and therefore highly esteemed by practicing physicians. Curschmann had a vigorous personality and knew how to exert his full authority in every position. In addition he was a very politic man. He had formed the greatest school of all living German clinicians and thanks to his influence and the worth of his pupils, most teaching positions in internal medicine were occupied by his pupils, as for instance, Krehl in Heidelberg, Romberg in Tübingen, His in Berlin, Hirsch in Göttingen. Presumably he will be succeeded by one of his pupils.

Professor Edlefsen of Hamburg, died a few days before Curschmann, at the age of 68. He was for a long time professor extraordinary of medicine at Kiel and had charge of the medical policlinic at that place. He was the author of a Text-Book of Diagnosis of Internal Diseases (Lehrbuch der Diagnostik der Inneren Krankheiten). His chief work lay in the field of pulmonary diseases. Some years ago he resigned his position at Kiel and took up his residence at Hamburg.

At the end of the summer semester Professor Leber, director of the university eye clinic at Heidelberg, will retire from his professorship.

Professor Verworn of Göttingen has received a call to Bonn as successor of Pflüger. Professor Heller, director of the pathologic institute of Kiel, celebrated his seventieth birthday, May 1.

International Exposition of Hygiene at Dresden

A short time ago it was determined to establish a special department in the exposition which should point out to the public the dangers which threaten it on account of quackery. The collection of the German society for the suppression of quackery is to serve as a nucleus for this part of the exposition; a call will be issued for other material.

Berlin University Centennial

The city government has appropriated $48,000 (200,000 marks) for the celebration of the jubilee of the university in October. Out of this sum such attendants of the university are to be taken care of as have shown themselves capable, have completed their academic education and can show that their further education will be improved by travel for study.

Tuberculosis Meetings

This week, as is the annual custom, various meetings for the campaign against tuberculosis have occurred, especially a general session of the German central committee for the campaign against tuberculosis, a session of the executive section of the central committee and a session of the commission appointed by the central committee for the campaign against lupus. For lack of space I will postpone the report of these very interesting meetings until my next letter.

VIENNA LETTER

(From Our Regular Correspondent)

VIENNA, May 10, 1910.

A Tariff of Medical Fees

The fight which the medical profession is prepared to carry on against the ruinous legislation called "social reform" requires organization and money. As about 90 per cent. of all practitioners belong already to the organization, the strike, if declared, will be rigidly adhered to and no club work will be done by doctors. In order to enable the doctors to deal with the population fairly, in case of club strike, the following tariff has been worked out for the country districts, with the strict understanding that no practitioner will be allowed to charge less:

The population will be regarded from the standopint of income. Persons or families with less than $250 (1,200 crowns) a year income, will be charged 20 cents (1 krone) per visit at the surgery; 50 per cent. more for a visit in the house of the patient, a moderate charge of 40 cents extra being added for each half hour's ride or drive. If the income be between $250 and $500 (teachers, clerks, better class of laborers) the tariff is 30 cents and 40 cents respectively for a visit, and 60 cents per half-hour drive. Persons with an income of more than $500 (2,400 crowns) or from another doctor's district will be charged 40 cents for consultation at the surgery, 50 per cent. more for a visit at the patient's lodging, and 80 cents per half-hour drive. Carriage charges are always to be paid by patient; night calls always 100 per cent. more; special hours, immediate calls 50 per cent. above ordinary fee. Consultations with the house physician are to be charged for respectively at $1.10, $1.60 and $2, and at least $2 for the consultant. The tariff will come in force on the day that the practitioners refuse all Krankenkasse or club practice; it is a litle higher than the usual fees charged in our country, in the upper limit at least, but it is very moderate in the lower limit, so as to give the poorer classes still the opportunity of obtaining medical help without the clubs. The population are informed already that this attitude of the profession has been caused by the threatening law, which will make private practice among the lower middle classes practically impossible.

The New Infants' Home in Vienna

In this country the government has taken over the charge of all orphans and foundlings and altogether over 17,000 children up to 14 years of age are at present under control in Lower Austria alone. For the purpose of dealing with foundlings in Vienna, a large up-to-date institution, the "Central Kinder-Heim" (Central Children's Home), has been erected and was recently opened by the emperor. It consists of a large building, capable of accommodating 410 children, besides 280 wet-nurses and mothers, and 54 nurses. The institution contains also a pavilion for diseased children, an isolation ward, and a reception ward for foundlings, where they are prepared, washed and brought into a condition of fitness for the home. Special care has been taken to ensure a sufficient supply of light and air to all rooms, and the chimney has been fitted with a smoke-destroying apparatus—the first instance of a large institution being provided with such an appliance in this city. The laundry handles 3,500 pounds of linen daily, and the kitchen prepares food for 600 persons. The elaborate plans, together with the grounds and building, were selected by a commission in which medical men had a deciding vote, and all children who are born in the clinics may have the first opportunity to be received there. Besides the institution negotiates positions for wet nurses, contains an information-bureau for mothers (hitherto a private affair of small associations), and all children controlled by the institute are cared for until they find employment or up to the age of 18.

Pharmacology

BROMIN-IODIN COMPOUND

The Life-History of a Nostrum

A correspondent writes for information concerning a remedy known as Bromin-Iodin Comp., which he says is manufactured by the Bromin-Iodin Chemical Company, formerly of Binghamton, N. Y., but now located in San Diego, California. In THE JOURNAL for Feb. 5, 1898, appeared an article by Dr. C. W. Ingraham, Binghamton, N. Y., entitled "Five Years' Successful Experience with a Special Mode of Treating Pulmonary Tuberculosis." This "special mode" of treatment consisted in using what Dr. Ingraham called "bromin-iodin compound," which he said had the following formula:

Iodin	gr. 1/2
Bromin	gr. 1/14
Phosphorus	gr. 1/100
Thymol	gr, 2/3
Menthol	gr. 2/3
Sterilized oil	fl. dr. 1

This "hypodermic treatment of phthisis" was widely advertised in the late nineties by the Bromin-Iodin Chemical Co., Binghamton, N. Y., and was but one of the innumerable "treatments" for pulmonary tuberculosis that have risen, had their day and, more or less gracefully, retired. It was first sold "to physicians only" for hypodermic administration. In 1906, however, physicians were told by the company that "if we find it impossible to secure your cooperation . . . we will be compelled to do business with the druggists in your locality. . . ." Apparently they found such cooperation impossible, because a leaflet was issued to the laity and the statement was made that they intended to advertise "all over North America in publications of national and international circulation, as well as in local newspapers. . . ." Naturally the laity couldn't be expected to administer this treatment by the hypodermic method and it is not surprising to read that "experiment has proved that the same solution can be taken internally." In addition to the advertising leaflet, the public also was provided with a "pocket calendar good for 200 years" which contained numerous testimonials from physicians laudatory of the "bromin-iodin" treatment. The layman who received one of the leaflets was told that if he was suffering from "asthma, bronchitis, colds, consumption, coughs, eczema, goiter, hay fever, neuralgia, rheumatism . . . also constipation and kidney troubles," and his recovery was "not as rapid as it should be," should, moreover, his physician refuse to use the bromin-iodin compound "it might not be a bad idea to discharge him" and get a physician who would!

At the time this "treatment" was first tried by its "inventor," the results given in fifty cases were: First stage, 91 per cent. cures; second stage, 50 per cent. cures; third stage, no cures, but improvement in several cases; this was in 1895. It now appears that this "treatment" has after a period of "patent medicine" exploitation come back into the "ethical proprietary" field. Presumably a mixture such as that represented by the "formula" did not lend itself to administration by mouth; there was nothing to do, therefore, but enlist the aid of "easy" physicians in furthering its sale.

THE PHARMACOPEIAL CONVENTION OF 1910

No one can predict the ultimate results of the action of the convention which has now passed into history; but for the benefit of those who did not attend the deliberations it may not be amiss to analyze those immediate results which affect the medical profession.

1. *The Election of Officers and the General Revision Committee:* This reflects fairly the composition of the convention, and this was overwhelmingly pharmaceutical. On the general revision committee of 50, there are only about 3 practitioners and about 6 pharmacologists. The other 41 members are pharmacists or chemists. Professor Remington, the chairman of the last revision committee, was reelected to the same position, and there is every reason to believe that he will endeavor to carry out the intentions of the convention fairly and efficiently.

2. *Delegates:* Delegates of certain government services and other organizations recommended by the trustees were admitted. An attempt to grant recognition to the National Association of Retail Druggists was defeated. The last action may be interpreted largely as a rebuke to the "patent-medicine" activities of the "American Druggists Syndicate."

3. *Number of Delegates from Institutions:* The recommendation of the trustees to restrict each institution to one delegate was defeated. This matter has two sides: The admission of three delegates means that the convention is representative of the individual delegates rather than of the institutions from which they are accredited; it places the medical institutions at a disadvantage; and it gives a very great advantage to the eastern institutions over those which are situated at a greater distance from Washington. On the other hand, it was argued that the eastern pharmaceutical men actually perform the greatest part of the work of revision; and that the three-delegate plan assured a larger convention. On the whole, it appears that the retention of three delegates is to be regretted.

4. *The Re-Formation of the Revision Committee:* The proposition of the trustees was carried to enlarge the general revision committee from 25 to 50; this committee to select from their own number an executive committee of fifteen. The latter are to have the charge and responsibility of the actual work of revision, while the other members will serve in an auxiliary, advisory, and supervisory capacity. It remains to be seen how this new plan will work in practice. I

it is carried out in the spirit in which it was intended—and there is every indication that this will be done—it gives promise of great usefulness. As has often been said, the old number of 25 members was too small to be representative, and too large for effective team work. The new plan secures both objects: The "General Revision Committee" is sufficiently large to really represent the convention—in fact, it makes the convention a permanent body. It can inquire into technical matters; it can advise and supervise; it can discuss questions of policy as they arise; it can help to secure publicity for such discussions; and it can aid in many other ways, and thus carry on the functions which would devolve on the convention if it were in permanent session. The convention has wisely given a very wide latitude to this general revision committee. On the other hand, the "Executive Revision Committee" can now be elected at leisure, each man for his especial fitness for his especial task. Having thus the full responsibility, as well as the full credit, for his part of the work, he will have every incentive to put forth his best individual efforts.

5. *Supplements:* The decennial revision has been justly criticised as too infrequent, at least too inelastic, for these days of rapid progress. This has been remedied by granting authority to the committee "to prepare a supplement to the Pharmacopeia at any time they may deem such action desirable."

6. *Publicity:* The universal demand for adequate publicity of the progress of revision has been met by the necessary instructions to the committee.

7. *Therapeutically Suggestive Titles, and Compound Preparations:* The Committee was instructed to eliminate these as far as possible. This is certainly a step in the right direction.

8. *Biologic Products and Biologic Assays:* The Committee was given authority to admit sera and other biologic products, as also *biologic assays of drugs.* The presence on the revision committee of an eminent serum expert, and of several pharmacologists who have had a large experience in pharmacological assaying, gives assurance that this work will be done scientifically. It was also decided to include in the Pharmacopeia *reagents which are important for clinical diagnosis.*

9. *Other Instructions in the Interest of Physicians:*

(a) Official Abbreviations: These are to be appended to all articles which are used in prescriptions. Their adoption by physicians will be optional, of course, but it will tend to prevent mistakes.

(b) A list of official preparations, in which each article is used, is to be appended.

(c) Doses: The experiment of stating the "average dose," which was made in the last revision, has been found acceptable; but the medical delegates were as a unit against the recognition of official "maximum doses," and a motion to introduce these was lost after a thorough discussion.

The "plan for revising the next Pharmacopeia," submitted by the retiring revision committee, in which the above recommendations were presented, also contained a considerable number of other valuable features of more strictly pharmaceutical interest, all tending to the improvement of the following revision, and all of which were adopted. Indeed, every item of this model report should have been adopted—but it was not to be. One clause only, and that in many ways the most significant, was voted down; namely, that relating to the

10. *Scope of the Pharmacopeia:* It was recommended that "there should not be included rarely used substances or *those whose value and use has not been established.*" Had this recommendation been adopted, and conscientiously carried out, the next Pharmacopeia would have been scientific in its contents as well as in its descriptions. It would have become a useful book medically as well as pharmaceutically. It would have become a guide to scientific prescribing. The reports of the various sections of the American Medical Association, and the replies to the circular sent out by its Committee on the Pharmacopeia, leave no doubt that this restriction was the desire of the medical profession. Teachers of therapeutics and of pharmacology foresaw that a restricted pharmacopeia would encourage a more careful study and a more extended use of the efficient and standard remedies.

The pharmaceutical profession, on the other hand, believed that its interests would be better served if admissions to the Pharmacopeia were governed by commercial expediency rather than by scientific merit. This policy is doubtless short-sighted, for the restriction of our overburdened materia medica is quite as much to the interest of the pharmacist, as of the physician and the public. However, the majority of the pharmaceutical delegates did not see it in this light. Had there been an adequate representation of physicians in the convention, they could doubtless have carried the point. In fact, the arguments for a therapeutically scientific pharmacopeia were so strong that a motion was defeated to substitute the words "value *or* use" as defining the scope. The convention did not care to go on record as discouraging scientific standards of admission! However, the majority were only too glad to avail themselves of the subterfuge of silence, by striking out the entire clause and thus leaving the determination of the scope to the general committee on revision.

This appears to leave the question open, but the committee doubtless understands what it is expected to do in the matter.

If the admissions to the future Pharmacopeia are not to be based on scientific standards; if the wishes of the profession are not to be recognized in its revision, then the book will not be regarded by intelligent physicians as a safe guide to scientific prescribing. The Pharmacopeia will always be important for enforcing standards of purity for drugs, but this practically will be the extent of its usefulness to the medical profession. The much greater field which we hope for it will have to be abandoned should this interpretation of the scope of the Pharmacopeia be accepted by the revision committee, which we trust will not be the case.

Correspondence

A Rapid Stain for Frozen Sections

To the Editor:—I was interested to note in The Journal (May 14, 1910, p. 1614) the rediscovery of an old method for staining frozen sections with thionin which I published in the *Proceedings of the New York Pathological Society* of 1901 (New series, i, 110). I can add that in an experience of ten years with this and other stains I have seen no reason to change the method as published, and can agree with Dr. Strouse as to its general applicability.

It is also interesting to record that surgeons are beginning to feel that they cannot always make a diagnosis of the exact nature of a tumor during operation, and are calling more and more on the microscopic expert to furnish accurate information. Suitable frozen sections are, in the vast majority of cases, as satisfactory for diagnostic purposes as those made after embedding and sectioning in the usual fashion; but it should be clearly understood that a man must have considerable training in this line of work before his diagnoses become reliable. Experience with thin sections stained with eosin-hematoxylin does not necessarily fit one for a diagnosis on thicker fresh sections.

I cannot, therefore, agree with Coplin, who says in Keen's "Surgery" (v, 1208), that "for diagnostic purposes the freezing method cannot be considered satisfactory," but hold with Wilson of Rochester, Minn., that the procedure is most useful and that errors do not occur if reasonable care is taken.

Francis C. Wood, New York.

To the Editor:—My attention has been called to Dr. F. C. Wood's report in the *Proceedings of the New York Pathological Society*, 1901, new series, vol. i, on the use of thionin as a stain for frozen sections. As I did not refer to this paper in my article on the same subject in The Journal (May 14, 1910, p. 1614), will you kindly allow me space to express regrets at my inability to find Dr. Wood's report before mine was published, and to state that while my work was independent, all credit for the use of the stain should belong to Dr. Wood?

S. Strouse, Chicago.

Resolutions Not Adopted

To the Editor:—I notice in the *New York Medical Record* of May 28 an item stating that certain resolutions presented by Dr. G. Frank Lydston to the House of Delegates of the Illinois State Medical Society at its last annual meeting were adopted.

I desire to call attention to the fact that this statement is not true. The facts are these: Dr. Lydston presented the resolutions to the House and moved their adoption. While this motion was pending a motion was made and carried to adjourn. The presiding officer declared the motion carried and adjourned the House. After the adjournment, and after most of the delegates had left the hall, a small number, 18 to be precise (20 being a quorum), most of whom I believe were from Chicago, held a meeting and called the second vice-president to the chair. He put the motion on the adoption of the resolutions presented by Dr. Lydston and declared them adopted. This meeting of 18 delegates out of 102 delegates present before adjournment cannot be considered a legal session of the House of Delegates of the Illinois State Medical Society.

E. W. Weis, Secretary Illinois State Medical Society.

Book Notices

Surgical Diagnosis. By Alexander Bryan Johnson, Ph.B., M.D., Professor of Clinical Surgery in the Columbia University Medical College. Vol. III. Cloth. Pp. 708, with 275 illustrations. Price, $6.00. New York: D. Appleton & Co., 1909.

Of the numerous conditions dealt with in the third and final volume of this work, particular mention may be made of the chapters on "Injuries and Diseases of the Spine and Spinal Cord" and on "Traumatic Neuroses" in which these rather obscure conditions to most general practitioners are very clearly described. The tuberculin tests for tuberculosis are considered here, having been purposely omitted from the other volumes in order that the last word might be given concerning their method of application and their value as a diagnostic measure. The dangers attending the conjunctival method are clearly set forth.

In an appendix is found some of the latest information concerning the parathyroid glands, exophthalmic goiter and hyperthyroidism, the status lymphaticus, the serum diagnosis of syphilis, recent improvements in *x*-ray apparatus and *x*-ray technic, and some additional data in regard to the diagnosis of organic lesions of the brain, thus bringing the subjects right up to the time of going to press. There is an index of authors and a very elaborate index of subjects occupying 90 pages. This is one of the best works on general surgical diagnosis that has appeared up to date.

Atlas zur Mikroskopischen Diagnostik der Gynäkologie. Nebst einer Anleitung und erlauterndem Text. Von Priv.-Doz. Dr. Rudolph Jolly, Oberarzt der königl. Universitäts-Frauenklinik zu Berlin. Paper. Price, 17.50 marks. Pp. 83, with 54 illustrations. Berlin: Urban & Schwarzenberg, 1910.

This atlas of the microscopic diagnosis of gynecology by Rudolf Jolly, includes an introduction, the application and technic of the microscopic examinations of specimens, and an explanatory text. The contents have been so systematized and simplified, and generously illustrated with pathologic sections with both high and lower power reproductions, that they are quite as invaluable to the general practitioner as to the gynecologist. The entire field of gynecologic pathology is covered, including plates of chorionic villi and decidual cells, mucous membrane and epithelium of the normal uterus, and the various stages of normal menstruation. It is illustrated with 52 exceptionally good colored plates. The explanatory notes are concise, and their meaning is clear. The author begins with the physiologic conditions, gradually develops into the simple, then the more complicated pathology, and finally brings out the differentiations. Each illustration, however, is complete in itself. The clearly defined lines drawn between the early malignant and benign growths is sufficient to make a valuable place for the work in the doctor's library.

The book is well worth possessing, even by those who do not read German, for the illustrations alone. Those who read German with difficulty will find that the book is written in a simple, easily comprehended style.

The Public Service

Medical Department, U. S. Army

Changes for the week ended May 28, 1910:

Pierson, Robert H., capt., left Vancouver Barracks, Wash., for duty at target range near Proebstel, Wash.

Oliver, Robert T., E. S. D. S., left Fort Hamilton, N. Y., en route to Fort Totten, for temporary duty; arrived at Fort Totten same date.

Walkup, Joseph O., 1st lieut., M. R. C., left Fort Snelling, Minn., with Battery D, 5th Field Artillery, en route to maneuver tract, Sparta, Wis.

Keefer, Frank R., lieut. col., relieved from duty at Fort Wadsworth, N. Y., and ordered to West Point, N. Y., for duty as surgeon and professor of Military Hygiene, relieving Lieutenant Colonel Charles M. Gandy, Medical Corps.

Hill, Eben C., lieut., sick leave extended 1 month.

Hess, Louis T., major, relieved from duty at Fort Leavenworth, Kan., and ordered to Fort Hamilton, N. Y., for duty.

Fuller, Leigh A., major, relieved from duty at Fort Hamilton, N. Y., and ordered to Fort Leavenworth, Kan., for duty.

Lambie, John S., Jr., lieut., relieved from further duty in the Philippines Division and assigned to duty as surgeon of the U. S. A. T. *Sherman*, with station at San Francisco.

Whitney, Walter, 1st lieut., M. R. C., left Fort McPherson, Ga., en route to U. S. Rifle Range, Waco, Ga., for duty with 3rd Battery, 17th Infantry.

Woodall, William P., capt., is assigned to the command of the one-half of Co. A, Hospital Corps, which is to participate in the camps of instructions at Fort D. A. Russell Target and Maneuver Reservation, Wyo., and Fort Riley, Kan., July 18 to Sept. 15, 1910.

Gray, William W., col., on arrival at San Francisco, will proceed to St. Paul, Minn., and report in person to the commanding general, Department of Dakota, for duty as chief surgeon of that department.

Connor, Clarence H., capt., after arrival at San Francisco, and on expiration of leave of absence will proceed to Fort Brady, Mich., for duty at that post.

Van Kirk, Harry H., 1st lieut., M. R. C., relieved from duty at Fort Levett, Me., and directed to proceed to Manila, P. I., for duty on transport sailing from San Francisco about Aug. 5, 1910.

Wall, Francis M., 1st lieut., M. R. C., relieved from duty at Fort Michie, N. Y., and directed to proceed to Manila, P. I., for duty on transport sailing from San Francisco about Oct. 5, 1910.

Huff, John Van R., col., ordered to inspect hospital and medical departments at Forts H. G. Wright, Terry and Michie, N. Y.; Mansfield, R. I.; Trumbull, Conn.; Adams and Greble, R. I.; Rodman, Banks, Andrews, Strong, Warren and Rever, Mass.

Wallace George S., 1st lieut., M. R. C., detailed as instructor of infantry officers of the organized militia of the State of Texas, Camp Mabry, Austin, Tex., June 6 to 11, 1910.

Graham, George D., dental surgeon, returned to Fort Des Moines, Iowa, from leave of absence.

Macy, Frederick S., lieut., granted 14 days' leave of absence.

Bingham, E. G., capt., reports relief from duty as Attending Surgeon, Headquarters, Department of California, San Francisco.

Long, Charles J., dental Surgeon, reported for duty at Fort Adams, R. I.

Shugerman, Harry P., 1st lieut., M. R. C., is relieved from duty at the Army Medical School in this city; he will proceed to his home and on arrival report by telegraph to The Adjutant General of the Army for further orders.

Medical Corps, U. S. Navy

Changes for the week ended May 28, 1910:

Pleadwell, F. L., surgeon, detached from the Naval Medical School, Washington, D. C., and ordered to the summer conference at the Naval War College, Newport, R. I.

Halton, E. P., acting asst-surgeon, ordered to duty at the Naval Hospital, Narragansett Bay, R. I.

Public Health and Marine Hospital Service

Changes for the week ended May 25, 1910.

Pettus, W. J., asst.-surgeon general, granted 1 day's leave of absence, May 24, 1910.

Banks, C. E., surgeon, granted 1 day's leave of absence, May 24, 1910.

Young, G. B., surgeon, detailed to represent the Service at the sixty-first annual meeting of the American Medical Association, to be held in St. Louis, June 7-10, 1910.

Lavinder, C. H., P. A. surgeon, granted 3 days' leave en route in Europe, under Paragraph 189, Service Regulations.

Korn, W. A., P. A. surgeon, granted 14 days' leave of absence from June 21, 1910.

Long, J. D., P. A. surgeon, directed to proceed to Philadelphia, Pa., on special temporary duty.

Lloyd, B. J., P. A. surgeon, granted 1 month's leave of absence from May 20, 1910, on account of sickness.

Mullan, E. H., P. A. surgeon, relieved from duty at Montreal, Canada, and directed to proceed to Ellis Island, N. Y., and report to the chief medical officer for duty.

Marshall, E. R., asst.-surgeon, relieved from duty at Delaware Breakwater Quarantine Station and directed to proceed to Honolulu, Hawaii, and report to the chief quarantine officer for duty.

Diaz, Jose A., acting asst.-surgeon, granted 30 days' leave of absence, without pay, from May 15, 1910.

Duncan, Wm. A., acting asst.-surgeon, granted 30 days extension of leave from April 4, 1910, on account of sickness.

Dunn, James, acting asst.-surgeon, granted 12 days' leave of absence from June 1, 1910.

Slamberg, N. L. A. K., acting asst.-surgeon, granted 30 days' leave of absence from May 25, 1910.

Tarbell, B. C., acting asst.-surgeon, granted 1 day's leave of absence, June 19, 1910.

Thornton, M. J., acting asst.-surgeon, granted 1 day's extension of leave, May 8, 1910, on account of sickness.

Wakefield, H. C., acting asst.-surgeon, granted 13 days' leave of absence from June 13, 1910.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

WARMED ANESTHETIC VAPORS

To the Editor:—Please give authorities in regard to the use of warmed anesthetic vapors or gases. ANESTHETIST.

ANSWER.—

Haun: "Advantages of Warming Chloroform for Anesthesia," München. med. Wchnschr., Nov. 26, 1907, No. 48.

Gwathmey, J. T.: "Warm versus Cold Anesthetics," New York State Jour. Med., February, 1908; abstr. in THE JOURNAL, April 4, 1908, p. 1150.

Report of the Anesthetic Commission of the American Medical Association, THE JOURNAL, Nov. 7, 1908, p. 1572 et seq.

McRoberts, W. J.: "An Advance in Anesthetic Technic," Northwestern Lancet, Aug. 15, 1909; abstr. in THE JOURNAL, Sept. 18, 1909, p. 970. This paper describes the method and the apparatus used for administering the warmed anesthetic.

DENTAL ANALGESIC

To the Editor:—As all country doctors have more or less extraction of teeth to do, it would be of interest to more than the writer if you would kindly publish formula for a safe and efficient analgesic. Please state amount to be injected. A. E. L.

ANSWER.—The following solution for injection for the production of local anesthesia is recommended by an authority on dental materia medica and therapeutics:

℞	gm. or c.c.		
Cocainæ hydrochloridi	|3		gr.v
Sodii chloridi	|25	or	gr.iv
Aquæ destillatæ	30|		fl℥ i

M. Sig: Cocain injection for dental purposes; to each c.c. add 1 drop of epinephrin solution (1-1000) when used.

For pain after extraction, cotton saturated with chloroform or ether may be applied to the cavity.

Marriages

HARVEY GORDON MCNEIL, M.D., to Miss Mary Jenks, both of Los Angeles, May 12.

THOMAS HENRY LEGG, M.D., to Miss Evelyn C. Repp, both of Union Bridge, Md., May 18.

EMILE E. DELANNEY, M.D., to Miss Margaret Mendenhall, both of South Omaha, May 14.

ARTHUR J. BOOKER, M.D., DesMoines, to Miss Daisy Deane Walker, of Indianapolis, May 12.

CHARLES REUBEN MCCREERY, M.D., Tacoma, to Miss Bertha F. Harris, of Seattle, May 14.

ALBERT E. BERNSTEIN, M.D., Detroit, to Miss Fannie Schomberger, of Traverse City, Mich., May 14.

EDGAR S. EVERHART, M.D., Crabtree, Pa., to Miss Madaline Lee Christian, of Richmond, Va., May 24.

CHARLES C. HEADLEY, M.D., Holloway, Ohio, to Miss Margarhetta Clemens, of Moorefield, O., May 11.

DANIEL JOHN KEELAN, M.D., Montgomery, Vt., to Miss Angeline Poronto, of Enosburg, Vt., May 10.

JOHN EGERTON CANNADAY, M.D., Charleston, W. Va., to Miss Margaret Stuart Roller, of Harrisonburg, Va., May 11.

ED HENRY SPIEGELBURG, M.D. Hot Springs, S. D., to Miss Maud Lee Talbott, of Boise, Idaho, at Hot Springs, May 9.

Deaths

Henry Sayles Kilbourne, M.D. University of Michigan, Ann Arbor, 1865; a member of the American Medical Association; who served as contract surgeon in the United States Army during the Civil War and at intervals thereafter until 1875, when he was appointed assistant surgeon in the regular establishment; was made captain in 1880; promoted to major in 1894; served during the Spanish-American War with troops at Tampa, Fla., and as chief surgeon of the Second Division, Fifth Army Corps in Cuba during the Spanish-American War; was promoted to Deputy Surgeon General with the rank of Lieutenant Colonel in 1903, and was retired from active service, Aug. 14, 1904; died at his home in Washington, D. C., May 16, aged 69.

Daniel Mayer, M.D. Eclectic Medical Institute, Cincinnati, 1869; of Charleston, W. Va.; a member of the American Medical Association, and formerly president of the West Virginia State Medical Association; a surgeon of volunteers during the Civil War, and at one time state commander of the G. A. R. of West Virginia; who was appointed by President McKinley consul-general to the Argentine Republic; died in the Jewish Hospital, Cincinnati, May 20, from nephritis, aged 73.

Oliver Payson Rex, M.D. Jefferson Medical College, 1867; hospital steward of the Thirty-third Illinois Volunteer Infantry; and later Major and Surgeon during the Civil War; for several years a lecturer on children's diseases in Jefferson Medical College; a resident of Abington, Pa., and medical director for several years of the Penn Mutual Life Insurance Co.; died May 16, on a steamer in which he was returning home from the Mediterranean, from pneumonia complicating typhoid fever, aged 63.

F. Gurney Stubbs, M.D. Northwestern University Medical School, 1893; a member of the American Medical Association, Chicago Laryngological and Rhinological Society, and Physicians' Club of Chicago; assistant professor of laryngology and otology in Rush Medical College; professor of laryngology, rhinology and otology in the Chicago Eye, Ear, Nose and Throat College; died in St. Luke's Hospital, May 26, from pneumonia, aged 41.

Frank Monroe Tiffany, M.D. University of Pennsylvania, Philadelphia, 1896; a member of the American Medical Association and a fellow of the American Academy of Medicine; a member of the staff of the Stamford (Conn.) Hospital and Children's Home; consulting physician to the Stamford Day Nursery, and physician in charge of St. John's Church and Home; died at his home in Stamford, May 18, from cancer, aged 41.

Clarence Samuel Bartlett, M.D. Dartmouth Medical School, Hanover, N. H., 1902; a member of the American Medical Association and New Hampshire and Massachusetts medical societies; from 1894 to 1906 a member of the staff of the New Hampshire State Hospital, Concord; a member of the Medical staff of the Henry Haywood Memorial Hospital, Gardner, Mass.; died recently at his home in that city, aged 41.

William R. Howard, M.D. College of Physicians and Surgeons, Baltimore, 1879; a member of the Medical Society of the State of New York, and one of the charter members of the Rochester Pathological Society; a member of the staff of St. Mary's Hospital and surgeon to the Buffalo, Rochester and Pittsburg Railway; died at his home in Rochester, May 22, aged 54.

Monroe Griffith Reynolds, M.D. Rush Medical College, 1880; of Aledo, Ill.; a member of the Illinois State Medical Society; and formerly president of the Mercer County Medical Association; representative in the Illinois General Assembly in 1904-1906, and Mayor of Aledo from 1899-1901; died suddenly on his farm near Redwood Falls, Minn., May 13, aged 64.

Rob Roy Kennedy, University of Nebraska, Omaha, 1902; formerly registrar of the State Board of Health, District 41, Nebraska; city physician of Murray, Utah; died in St. Mark's Hospital, Salt Lake City, March 28, from cerebral embolism after an operation for nephrectomy and appendicectomy, aged 35.

Thomas H. Daugherty, M.D. Cincinnati College of Medicine and Surgery, 1866; a member of the Kentucky State Medical Association; for many years a practitioner of Sadieville, Ky., and president of the Sadieville Deposit Bank; died at his home in Georgetown, May 19, from heart disease, aged 63.

Edward R. Perkins, M.D. Hahnemann Medical College, Philadelphia, 1878; a veteran of the Civil War and for more than 30 years a practitioner of Excelsior, Minn.; died suddenly May 21, on a Lake Minnetonka car, while making a professional call, from cerebral hemorrhage, aged 67.

Michael Brinkmann, M.D. University of Marburg, Germany, 1848; surgeon in the German Army in 1848 and 1849, and assistant court physician in 1850; said to have been the first to introduce hydrotherapy in the United States; died at his home in Philadelphia, May 19, aged 84.

Wilton Winston Winget, M.D. Miami Medical College, Cincinnati, 1893; a member of the Oklahoma State Medical Association; died at his home in Nowata, May 14, from the effects, it is said, of a hypodermic injection of medicine administered to cure the morphin habit, aged 41.

Henry Proper Stillwell, M.D. University of Buffalo, N. Y., 1879; a member of the Medical Society of the State of New

York, and vice-president of Schuyler County Medical Society; died at his home in Burdett, April 9, from cerebral hemorrhage, aged 64.

Jacob S. Giltner, M.D. Pennsylvania Medical College, Gettysburg, 1846; medical director of the Army of the Cumberland during the Civil War, and a practitioner of Portland, Ore., since 1866; died at his home, May 18, from cerebral hemorrhage, aged 85.

James Bourne Ayer, M.D. Harvard Medical School, 1873; a member of the American Medical Association; formerly an overseer of the poor at Boston and a member of the State Board of Insanity; died at his home in Boston, May 14, aged 60.

William G. Gardiner, M.D. Toledo, Ohio, Medical College, 1883; formerly demonstrator of physiology and anatomy in his alma mater; a member of the American Medical Association; died at his home in Toledo, May 18, from pneumonia, aged 69.

Thomas Drury Edwards, M.D. University of Tennessee, Nashville, 1884; a member of the American Medical Association, and a specialist in disease of the eye; died at his home in Union City, Tenn., May 16, aged 53.

Martin A. McHenry, M.D. Tulane University, New Orleans, 1882; a member of the Louisiana State Medical Society, and a wealthy and prominent practitioner of Monroe; died at his home in that city, May 15, aged 55.

Edward C. Adams, M.D. Northwestern Medical College, St. Joseph, Mo., 1886; a specialist on diseases of the eye and ear of St. Joseph, Mo.; died in a hospital in that city, May 14, from cerebral hemorrhage, aged 52.

Sidney Bishop, M.D. Bellevue Hospital Medical College, 1873; an honorary member of the Bridgeport (Conn.) Medical Association; died at his home, March 24, in that city, from valvular heart disease, aged 62.

John W. Hebb, M.D. University of Maryland, Baltimore, 1860; a member of the Medical and Chirurgical Faculty of Maryland; died at his home in West Friendship, May 18, from senile debility, aged 71.

Joseph Solomon Morton, M.D. Rush Medical College, Chicago, 1887; a member of the American Medical Association; died while fishing near his home in Vernon, Ill., May 18, from angina pectoris, aged 46.

Francis X. Weil, M.D. University of Pennsylvania, 1869; a member of the Medical Society of the State of Pennsylvania; treasurer of York County Medical Society; died at his home in York, May 20, aged 69.

Joseph C. Kimsey (license, years of practice, Ind.); a practitioner of Steuben County for 54 years; a veteran of the Civil War; died at the home of his daughter in Angola, May 16, aged 90.

John G. Stricklett (license, years of practice, Ill., 1880); a practitioner for 52 years, and a veteran of the Civil War; died at his home in Springfield, May 8, from senile debility, aged 83.

William Dunstone (license, Mich., years of practice, 1900); for 44 years a practitioner of the Copper Country; died at his home in Dollar Bay, Mich., May 18, from senile debility, aged 79.

Newell Allen Dryer, M.D. University of Buffalo, N. Y., 1864; for 40 years a practitioner of Bath, Mich.; died suddenly in Perkins, Okla., April 23, from cerebral hemorrhage, aged 71.

Allen V. Sheridan, M.D. Kansas City, Mo., Medical College, 1899; of Broken Bow, Neb.; formerly of Paola, Kans.; died suddenly in that city, May 16, from heart disease, aged 41.

Frederick S. Gray, M.D. University of Vermont, Burlington, 1882; a member of the American Medical Association; died at his home in Troy, Vt., March 1, from diabetes, aged 53.

Simeon Joseph Gérouard, M.D. Laval University, Montreal, 1890; of Worcester, Mass., died in the Worcester City Hospital, April 3, from lobar pneumonia, aged 40.

Ezra L. Broughton (years of practice, Mich., 1900); of Lansing; died in the Michigan Asylum for the Insane, Kalamazoo, May 5, from arteriosclerosis, aged 74.

A. W. Manchester (license, Iowa, years of practice, 1886); for 35 years a practitioner of Walker; died at his home, May 14, from heart disease, aged 62.

Jacob P. McIntosh, M.D. Eclectic Medical Institute, Cincinnati, 1869; died at his home in Worthington, Ind., April 30, from senile debility, aged 74.

Arthur Wadsworth, M.D. Kentucky School of Medicine, Louisville, 1893; died at his home in Castleton, Ind., May 14, from heart disease, aged 52.

AMERICAN PEDIATRIC SOCIETY

Annual Meeting, held in Washington, D. C., May 3-5, 1910

(Continued from page 1712)

The President, DR. D. L. EDSALL, in the Chair

SYMPOSIUM ON POLIOMYELITIS

Infantile Poliomyelitis; Its Relation to the Community in Reference to Etiology and Prevention

DR. R. W. LOVETT, Boston: The medical profession of to-day is confronted with the task of making a new literature on the subject of infantile poliomyelitis, and of dealing with the various aspects of the disease as it affects the community. Orthopedic men who have to repair the damage done will be anxious to join hands with the pediatrists in fighting this malady. It is one of the most infectious diseases and is unquestionably on the increase. It is serious enough to warrant greater attempts on the part of health authorities to investigate the conditions under which it occurs. Information obtained in Massachusetts in the past year shows that the death rate is generally from 5 to 15 per cent. Of the patients who survive over four-fifths are permanently paralyzed and many crippled for life. The recognition of outbreaks of infantile poliomyelitis is of recent date. From the time of the report of the first outbreak until 1909 is only thirty years. Sixty-nine outbreaks have been reported all together. The outbreaks of the past five years show that it is not a local condition. The United States shows over one-half of the reported cases. There has been an increase in outbreaks in the last five years in a way not to be explained by increased interest in the disease. There are more in cold than in warm countries. More cases are reported in the United States than in other parts of the world.

It is evident that house-to-house investigations of all outbreaks should be made by competent men. The infectious nature of the disease has been demonstrated in the laboratory by Flexner and others, but I believe the work in the field to be of equal importance. Maps prepared by the State Board of Health of Massachusetts show the distribution of the disease there. One hundred and thirty-six cities and towns were listed according to the prevalence of the disease. Boston is shown by districts.

It is notable that density of population seems to have nothing to do with distribution. Most cases occur in old houses. Prevalence of the disease is shown not to be coincident with deficiency of rainfall. Out of 187 cases, 149 children were paralyzed. There were 48 abortive cases. More males than females were affected. Nearly one-half of the children had been wading or swimming in contaminated water before the onset of the disease. Only 7 per cent. occurred in first year of life, but 87 per cent. in the first ten years. Pain and tenderness occurred in a large percentage of cases. Duration of the paralysis was from three days to three months. No conclusions were drawn from the investigation, the report being entirely a preliminary one, but I think if the investigation of the disease by health authorities is to be continued it should be so indicated by the representatives of the societies present.

The Clinical Aspects of Poliomyelitis; Types; Communicability; Mortality

Dr. L. Emmett Holt, New York: There seems to be an alarming increase of epidemics of this disease. The infection, starting in Europe, is spreading over this country and probably over the entire world. There is no essential difference between the two forms of the disease, except as to communicability. The analogy to cerebrospinal meningitis is striking. Virulence is greater when the disease is epidemic, but otherwise they seem identical. The disease varies in severity in different epidemics. The death rate in sporadic cases is much lower than in the epidemic cases. The proportion of abortive cases cannot be estimated at present, but it is probable that the number is quite large. Several cases of transmission by a third party have been noted. The disease is contagious, and under certain conditions highly so, demanding in epidemic forms a strict quarantine. Healthy persons may be carriers of the infection. Contact with persons suffering from the disease, or associated with it, is the medium of infection. The disease seems to vary as to its communicability at different times. I believe that a new name should be sought for the disease, as the term used is not exact, inasmuch as it is not limited to the anterior horns, nor indeed to the cord itself. I suggest the name, epidemic myeloencephalitis.

Experimental Epidemic Poliomyelitis and Its Relation to Poliomyelitis in Human Beings

Dr. Simon Flexner, New York: In the last few months it has been demonstrated with certainty that a disease agreeing in clinical type and pathologic features with anterior poliomyelitis can be produced regularly in certain of the lower animals.

[The results of Dr. Flexner's experiments will be found in papers published in The Journal during 1909 and the present year.]

Paralysis of the Neck and Diaphragm in Poliomyelitis

Dr. Irving M. Snow, Buffalo: I wish to report such a case terminating in complete recovery in a boy of 4 years. There was pain, tenderness and retention of urine. In a day or two flaccid palsy of the neck occurred. There was complete paralysis of the neck muscles so that patient had no control of the head whatever. Most of the distress, however, was from difficulty in breathing. For ten days he remained in a stationary condition. On the fourteenth day of illness the patient improved, but the neck muscles remained paralyzed. A jury mast had to be employed for some time. I believe that cervical poliomyelitis, affecting only the spinal accessory nerve, is rare, and although paralysis of diaphragm is rare and dangerous, recovery is possible.

The Pathology of Poliomyelitis

Dr. Israel Strauss, New York, described in detail the lesions found in the disease, demonstrating them by means of many lantern-slides.

This is no longer a disease of doubtful origin, but is unquestionably due to infection. The virus reaches the meninges very early after infection. Infection may take place through the intestinal route. In regard to the experiments in which infection was produced by scarifying the nasal mucous membrane, that would seem to be really introducing the infection directly into the blood. I believe there is a strong resemblance between the virus and that of rabies. I wish to call attention to the interesting relations between the pathologic changes shown and the clinical picture of the disease. Many of the cells in the cord are not affected and can undergo rapid recovery. The extent of the paralysis gives no idea of the extent of the lesion, and I believe that in every case in which the cord is infected the bulb is also affected. The hope of the future is in finding a means for checking the disease before it has attacked the ganglion cells, and of finding the source of infection and preventing its spread.

Treatment for the Amelioration of Permanent or Partial Paralysis by Silk Tendons and Silk Ligaments

Prof. D. Fritz Lange, Vienna: In the acute stage, fixation, either in an orthopedic bed or plaster-of-Paris bandages, is a measure to be recommended. After the subsidence of the acute stage a second task develops for the orthopedist—to prevent the occurrence of contractions and interference with the nutrition of the affected muscles. I would warn you especially against rough, hard massage. The muscles may be weakened and injured instead of strengthened in this way.

[His method of employing silk tendons and silk ligaments was demonstrated on a model. He uses a celluloid support to prevent sinking of the arch of the foot and during the night uses a steel support. Where the muscle is too short he lengthens it by means of silk sutures.]

Discussion on Poliomyelitis

Dr. B. Sachs, New York: I rather think the name infantile spinal paralysis is the proper one clinically. Perhaps a more proper name from a pathologic standpoint would be polioencephalomyelitis. I consider that time given to massage and electricity in these cases is time wasted; I cannot see that such methods do any definite good, and a great deal more benefit would be attained by early institution of orthopedic measures. The atypical forms of the disease I believe are rare.

A Comparison in Boys and Girls of Weight, Height, Epiphyseal Development

Dr. Thomas Morgan Rotch, Boston: The series of charts exhibited here demonstrate that at first boys are heavier and taller than girls, but the girls' weight line crosses the boys' at about 13; the boys' again crosses the girls' at about 17. The line for height shows about the same thing. Age does not readily determine weight and height. Girls are lighter and shorter than boys at birth, but before puberty the girls gain. The charts show the lack of relationship between epiphyseal development and general growth. In grading individuals the epiphyseal development should replace chronologic grading. The child's welfare depends on maintaining a proper equilibrium, and there should be a curriculum adopted to certain stages of epiphyseal development.

The Cytodiagnosis of Tuberculous Meningitis and the Possibility of Recovery

Dr. Charles Hunter Dunn, Boston: The child whose illness forms the basis of my paper was a girl of 3 years of age. Father, mother and younger sister are well; brother died of tuberculosis of spine. There is nothing remarkable in previous history. December 5, two days before I saw her, she began to vomit; continued vomiting all day; at 5 p. m. vomiting ceased; next morning she was better and played a little; in afternoon vomited once. Temperature varied from 99 to 100. Increasing apathy was the most noticeable feature. She was a well-developed, well-nourished child, lying on her back, with eyes open, but took little interest in her surroundings; eyes fixed and staring; ptosis of left eyelid; no retraction of head; knee jerks somewhat more lively than normal; moderate Kernig. She was given castor oil and irrigation of colon until the following day. Then she began to cry out. There was marked rigidity of right arm and hand. She was seen again the following day; had had bad night; crying out and twitching of hands; temperature not above 100; apathy more marked; occasional slight internal strabismus; Babinski's sign present. Lumbar puncture; 10 c.c. cloudy fluid obtained; examination showed no fibrin formation; slide count showed 260 lymphocytes per cm., 2 per cent. polynuclears, 96 per cent. lymphocytes, 2 per cent. endothelial cells. With stain for tubercle bacilli several clumps of acid-fast bacilli were found which resembled tubercle bacilli. Positive diagnosis was made and unfavorable prognosis given. The condition cleared up and patient is now perfectly well. The evidence of the presence of the tubercle bacilli, with the other signs, is strong evidence of its being a case of tuberculous meningitis, and I believe we are justified in holding out some hope in these cases. If it were possible to demonstrate the bacilli in every case of lumbar puncture it would be of great value. The predominance of lymphocytes may be generally accepted as diagnostic. I have endeavored to establish a standard of the number of cells present in the fluid, and have found in sixty cases that the average is between 200 and 400 per cm. Should this be confirmed, it will give additional means of making positive the diagnosis of tubercular meningitis. It might lead to recognition of other cases of recovery in the future.

DISCUSSION

Dr. W. P. Northrup, New York: I have had one of these "don't-know" cases myself, but do not think one is justified in feeling sure of this diagnostic method. In my case the patient had all the symptoms of tuberculous meningitis, with increased fluid and increased lymphocytes on lumbar puncture, but the patient suddenly began to get better. Why, I do not know, so I refer to them as "don't know" cases.

Dr. F. S. Meara, New York: I have lately correlated the cases of meningitis in Bellevue for the past three years, and of fifty in which lumbar puncture was done in forty the bacillus was recovered. My results correspond closely with those of Dr. Dunn. One child under 1 year, in whom the bacillus was found in the fluid, improved after some weeks, and it was thought to be a case of recovery, but the child suddenly became worse and died. There were a number of cases of so-called meningismus in which there was slight increase in the cells.

Dr. S. M. Hamill, Philadelphia: I have not formally reported, but in a discussion referred to a case of tuberculous meningitis which I had under my care a few years ago in which the bacilli were recovered in the fluid and in which recovery occurred. There was slight increase of leucocytes and the tubercle bacilli were found. I had not laid particular stress on the case because no animal injections were made and so the final link in the chain of evidence was lacking.

Dr. J. P. Crozer Griffith, Philadelphia: Frebinger has reported finding the bacillis in a case in which the patient recovered.

Dr. F. S. Churchill, Chicago: The presence of lymphocytes is not sufficient; only the presence of the bacillus is positive proof.

Dr. Isaac A. Abt, Chicago: I believe that patients sometimes recover from tuberculous meningitis. In a case seen in Vienna the diagnosis was made and later, the child having died of another disease, the scars at the base of the brain were shown at autopsy, confirming the clinical diagnosis.

The General Considerations Regarding the Effects of Vaccines

Dr. S. M. Hamill, Philadelphia: Vaccine treatment differs in no way in children from that in adults, except in the matter of dosage. Relatively small minimum doses are generally advocated, but there is considerable difference of opinion as to maximum doses. The impressions one gathers are that it has been demonstrated that localized infections with staphylococcus pyogenes aureus are quickly cured; that generalized infections are favorably influenced; that gonococcal infections are favorably influenced; that in other diseases there is not enough data yet to warrant any striking conclusions.

(To be continued)

ASSOCIATION OF AMERICAN PHYSICIANS

Twenty-fifth Annual Meeting, held at Washington, D. C., May 3-5, 1910

(Continued from page 1807)

Clinical Significance of Transitory Delirium Cordis

Dr. George Henry Fox: By transitory delirium cordis is meant a transitory but extreme irregularity of the heart, during which the auricular waves disappear from the venous tracings. The paroxysms may be excited by exhaustion, vomiting, exertion or excitement, or they may come on with no apparent cause. In two patients, over 40, the first paroxysms occurred after operations. The heart may be absolutely negative on physical examination between attacks and the diagnosis of a nervous condition made. However, as five of the six patients ultimately developed the permanent form of irregularity with cardiac insufficiency the prognosis should be guarded.

DISCUSSION

Dr. Joseph H. Pratt, Boston: I have under observation now a case of the type described. The patient is 60; has never had any shortness of breath; he is well between attacks, except that he is nervous; no shortness of breath on exercise. A month or two ago I attended him in one of his attacks. His pulse was very irregular, and varied from 120 to 140 beats per minute. The attack lasted twelve hours. The tracings showed the heart sounds apparently duplicated. This condition might readily be mistaken for a cardiac neurosis.

Dr. Walter B. James, New York: From a study of 150 cases and cardiograms I am convinced that arrhythmia forms an important group of cases which has not been subdivided satisfactorily. There is no question whatever that a great number of these cases depend on auricular fibrillation. I believe that the use of the electrocardiogram is the only means of determining whether this is the case or not.

Relation of Combined Intoxication and Bacterial Infection to Necrosis of the Liver, Acute Yellow Atrophy and Cirrhosis

Dr. Eugene L. Opie, New York: By the administration of poisons which attack the liver, namely, chloroform or phosphorus, in combination with bacterial infection, it is possible to reproduce the peculiar midzonal necrosis which in man occurs in association with bacterial infection, under conditions which are not fully understood. The same combination of poison and bacteria, apparently acting with maximum intensity, reproduces a lesion resembling acute yellow atrophy in man; necrosis and hemorrhage are followed by regenerative changes. When the poison in association with bacterial infection repeatedly produces relatively slight changes, cirrhosis of the liver occurs and advances much more rapidly than that produced by the poison alone.

DISCUSSION

Dr. S. J. Meltzer, New York: The results obtained by Dr. Opie are very practical and important, but I should like to offer a suggestion. His results were obtained by using chemicals on the one side and bacteria on the other. Some years ago I presented a paper before this association in which I pointed out certain facts now generally recognized, namely, that bacteria like the typhoid bacillus or streptococci when introduced into the circulation disappear in a very short time. But if there is a small injury inflicted, then these bacteria will start to develop. In Dr. Opie's experiments it might be the chloroform or the phosphorus that caused this injury.

Dr. William W. Welch, Baltimore: Experimental work on cirrhosis of the liver has hitherto been very unsatisfactory, particularly with alcohol. I have never succeeded in producing cirrhosis of the liver experimentally with alcohol. The liver has an enormous regenerative power, and in order to produce cirrhosis we must inhibit this regenerative power. A combination of the action of toxins with something which prevents this regenerative power may give the real explanation of the cause of cirrhosis of the liver.

Development of the Epiphyses of the Hand and Wrist

Drs. T. M. Rotch and H. W. Smith, Boston: During the past year work in this direction on boys and youths from 7 to 20 years of age has been carried on with the following results: It has been found that the development of the hand and wrist represents so well that of the other epiphyses of the skeleton that they furnish the best material for the study of epiphyseal development. It has been found that the epiphyses which appear first are the last to unite, so that the lower epiphysis of the radius has proved to be of especial value in this work since it appears so early and unites so late. It has been found that while the appearance of the carpal bones and epiphyses furnish us with an index for the first half of epiphyseal development, the uniting of the epiphyses of the radius, ulna, metacarpal bones and phalanges provide us with a means of establishing an index for the second half of epiphyseal development.

SYMPOSIUM ON INTRACELLULAR FERMENTS

Interpretation of the Metabolic Defects in Diabetes Mellitus

Dr. A. E. Taylor, Berkeley, Cal.: There are four chief reactions of glucose in the animal body; the formation of glucose from levulose and galactose, and the formation of galactose from glucose; the formation of glycogen from glucose, and the reversed reaction; the formation of fat from glucose; and the combustion of glucose. All are reactions of fermentation. On the basis of the nature of the chemical reactions involved, all are presumably related to different enzymes. Retained fully in true diabetes is the reaction of intramolecular conversion, the formation of glucose from levulose and galactose. More or less completely lost are the power of forming glycogen from glucose, of forming fat from glucose, and of burning glucose, especially the last. In the reaction of formation of glycogen from glucose are two stages known: the stage of disaccharide and of polysaccharide; we do not know where in diabetes the difficulty lies. The loss of the power of forming fat from glucose cannot be studied until we know whether normally sugar is formed from fat in the body. In the case of the loss of the power of burning sugar, it is known that the difficulty lies in the very first stages of the reaction, before the stage of lactic acid. The loss of power of forming glycogen and fat from glucose cannot be dependent on the loss of the power of burning glucose.

The loss of power of burning glucose is physico-chemically to be interpreted as follows: Glucose in alkaline reaction is slowly burned; this is the auto-reaction. The muscles provide a zymase, which is of low activity only. The pancreas, presumably the islands of Langerhans, provide a zymo-excitor, whose action is to multiply greatly the acceleration accomplished by the muscular zymase. A direct analogy is to be found in alcoholic fermentation, where the zymase of the yeast is the enzyme and phosphoric acid the zymo-excitor. Loss of combustion of glucose could be caused by loss in the mass of the muscular enzyme, by loss in the mass of the pancreatic zymo-excitor, or by some disturbance in the reaction. The best investigations indicate that in diabetes of the classical type, the cause is to be found in the pancreas, leading to a more or less complete reduction in the mass of the zymo-excitor.

The Internal Secretion of the Pancreas

Drs. J. H. Pratt and L. H. Spooner, Boston: Atrophy of the pancreas was produced by ligating the ducts in dogs and cats. Limit of assimilation of carbohydrates decreased 50 per cent. or more in two months after occluding the pancreatic ducts. In a dog kept under observation for one year, diabetes did not develop. There was no definite evidence of compensation on the part of other organs for diminished pancreatic function. Limit of assimilation for glucose was markedly increased by feeding fresh pancreases. In both dogs and cats there was complete disappearance of the islands of Langerhans in atrophied pancreases without the occurrence of diabetes.

Clinical Experiences with the Cammidge Reaction

Drs. D. C. Balfour, J. T. Pilcher, B. C. Willis and B. F. McGrath, Rochester, Minn.: Of 62 patients at operation showing involvement of pancreas, 50 gave more or less “positive reactions. Of 50 cases showing at operation no pancreatic involvement, seven gave more or less “positive” reactions. Of 25 “well” individuals one gave a “positive” reaction. This work served to show the possibilities of error owing to the indefiniteness of what actually constituted a reaction due to great variation in color changes, amount of precipitate, type of crystals and relation of controls. Additional cases studied later were clinically of four classes: I. Cases shown at operation or autopsy to have involvement of pancreas. II. Cases (with abdominal or pelvic lesions) which at operation or autopsy were shown to have no involvement of the pancreas. III. Sick individuals in whom the pancreas were not examined. IV. Apparently well individuals.

Of Group I (pancreas involved), containing 21 cases, 14 were examined before operation. Of these, 6 gave positive reactions. Of the same 21 cases examined five days after the operation 6 were positive, 3 of these having been positive before operation, 1 negative and 2 not previously examined. Eighteen of these cases were examined about the ninth day after operation, and 3 gave positive reactions. These 3 had all been positive at the examination before operation. One had been positive on the second test, and the other two negative.

Of Group II (pancreas not involved), containing 60 cases, 21 were examined before operation. Of these, 14 were positive. Five days after operation all 60 were again examined and 15 were positive. Four of these had been positive before operation and the remaining 11 had not been previously examined. About nine days after operation 55 of these cases were again examined. Fourteen were positive. Of these, 5 had been positive before operation and the remaining 9 not examined before operation. Nine of the 14 cases had been positive five days after operation.

Of Group III (sick persons whose pancreases were not examined) 207 cases were examined. Seventy-three of these were positive. Of these 73 positives 15 were goiter cases (31 goiter cases in all examined), 8 were appendicitis cases, and the remainder were cases of salpingitis, uterine tumors, etc.

Of Group IV (apparently well persons) 17 cases were examined from one to five times each. Of these, 5 were positive.

From the foregoing it is apparent that even where the most elaborate care is exercised to follow the technic of Cammidge's “C” reaction, in the most uniform manner, if knowledge of the clinical histories and other factors of the personal equation be eliminated, the end results, judged by Cammidge's own criteria, must be considered, as a means of diagnosing disease of the pancreas, as both valueless and misleading. There is no apparent clinical relationship between disease of the pancreas and any of the various types of end reaction. It does not seem that the end reactions are artefacts but rather that they indicate actual metabolic variations. The relationship of these changes in metabolism to the welfare of the patient is not apparent.

Discussion on Ferments

Dr. Francis P. Kinnicutt, New York: Our observations at the Presbyterian Hospital do not permit me to accept these conclusions. Our work is done most carefully, and the personal equation is eliminated. The examinations are made by one person who is an expert chemist in the laboratory and who has no knowledge of the cases. The specimens of urine are simply sent to him in the laboratory, and the improved Cammidge test is used in all cases. We have tried it very carefully in 127 cases. Among these there were positive reactions in 24, while in the remainder the reactions were negative.

Dr. L. A. Wilson: It seems to me that the results are far from proving that a positive test will demonstrate pancreatic lesions. Strange as it may seem, the test was positive in many healthy individuals. In patients with pancreatic lesions the reaction varied greatly. One day they would have a beautiful reaction; during the next twenty-four hours the specimen sent would show no reaction.

Bacteriology of Acute Respiratory Infections

Dr. L. Emmett Holt, New York: Nearly 1,000 cultures have been made from children, mainly hospital patients, these chiefly from the bronchial secretion. Cultures for the sake of comparison have been made from the nose, nasopharynx and pharynx. The organisms studied have been the pneumococcus, influenza bacillus, streptococcus, staphylococcus, tubercle bacillus and diphtheria bacillus. The persons are classified as: (1) healthy hospital inmates; (2) those suffering from acute illness, non-respiratory; (3) those suffering from mild acute respiratory infections; (4) pneumonia. An attempt has been made to connect the clinical symptoms with the bacteriologic findings. In most cases mixed infections were present. In many the pneumococcus, influenza bacillus or staphylococcus predominated and gave a definite clinical picture, temperature curve, etc. Infection with the *Bacillus* *influenza* was usually of a mild type, but with fairly characteristic symptoms and temperature; staphylococcus infections were *usually mild*, sometimes persistent streptococcus infections are uncommon as a predominant type.

A Clinical Method of Estimating the Coagulability of the Blood

Dr. R. D. Rudolf, Toronto: In this research the glass tubes introduced by Sabrazes and McGowan were used. These are tubes with a caliber of 1.5 mm. and a length of about 7 inches. They are partially filled with blood taken under certain precautions and after a few minutes are broken across at half inch intervals every half or quarter minute and the broken ends are slowly separated. When coagulation has occurred the blood column does not break with the glass as it does until then, but a thread of fibrin remains connecting the two parts of the broken tube.

About five hundred estimations have been made and the results are, under the same circumstances, very constant. No definite variations occur at different times of the day nor in relation to meals. The temperature at which the filled tubes are kept, however, makes a marked difference in the time of coagulation, this varying roughly about one minute for every degree Centigrade.

SYMPOSIUM ON VACCINE THERAPY

The Basic Principles of Vaccine Therapy

This paper by Dr. J. G. Adami, Montreal, will appear in full in The Journal.

Vaccine Therapy in Typhoid

Dr. M. W. Richardson, Boston: Typhoid vaccines are of the greatest value in prophylaxis, and should be made use of by all who are likely to be exposed to the disease. Their use by the general public cannot be expected in the near future. For this result, time and education will be required. Typhoid vaccines properly used will, I feel sure, prevent a large proportion of relapses. The success of vaccines in the treatment of the original disease will depend on the character of the case. Conservatively used they will do no harm and they may be of much assistance. Early diagnosis and early treatment will be, undoubtedly, of great importance.

Effects of Injections of Killed Streptococci in the Living Body

Dr. G. H. Weaver, Chicago: The galactose-killed germs are *more active than heat-killed streptococci. In erysipelas* they have no effect except in the subacute and *chronic* cases. In streptococcic complications of the eruptive diseases they have no effect in the acute stage, but in the subacute and chronic stages marked benefit is noted in some cases. The "septic" cases are often benefited. The difficulties in judging the results of injections are very great because of the natural course of the condition treated. Failure in favorable cases may depend on exhaustion of the reactive ability of the body cells, adaptation of bacteria, distortion of the interaction of bacteria and the serum and cells of the body.

Discussion on Vaccine Therapy

Dr. Frank Billings, Chicago: We have used vaccination in various forms of infections at the Presbyterian Hospital in Chicago with satisfactory results *in a certain* class of cases and very unsatisfactory results in others. *In acute* infectious diseases with severe clinical course, as pneumonia, typhoid and especially in chronic infectious endocarditis, *vaccination* certainly seems to do no good, but it does no *harm*. In genitourinary diseases, if there is a morbid condition of the kidney or ureter, or prostate, or if there is a pelvic condition in which there is a distortion of the bladder and poor drainage, *one can* continue vaccination forever and not drive the organisms *out*; but if the physical condition can be overcome, vaccination *may* cause the organisms to disappear. One may vaccinate *forever* and ever when there is a typhoid infection of the gall-bladder, without results. In infections of the antrum, unless it is properly drained, vaccination is of no value.

ILLINOIS STATE MEDICAL SOCIETY

Sixtieth Annual Meeting, held at Danville, May 17-19, 1910

(Concluded from page 1809)

Neurologic Conditions of Joint Diseases

Dr. Archibald Church, Chicago: The anatomic relations of joints and muscles which actuate the joints with the general mechanism of the nervous control give rise to certain functional points which are of importance in the consideration of *joint disease. In* other instances involvement of joints extends *to nerve trunks* in the vicinity, giving rise to symptoms of distal situation. These considerations are of particular importance in relation to neuritis secondary to joint involvement, this giving rise to neuritis due to the involvement of *the filaments* of the nerves within the joints and leading to secondary muscle wastings above the joints and secondly to the wasting below the joints when the nerves which pass the joints are implicated. Another group of joint disorders essentially hysterical in character, without any evidence of involvement of joint surface or joint mechanism, present features of distinctive significance. This condition may also be associated with actual joint lesions.

Joint Diseases from the Orthopedic Standpoint

Dr. John Ridlon, *Chicago: The mechanical treatment of* joint diseases is mainly confined to the treatment of tuberculous joints and to the deformities resulting from joint tuberculosis and other infections. In the mechanical treatment of tuberculous joint diseases one must consider the general principles, together with the relative value of fixation, traction, protection during certain stages, and the stimulating value of *the use of the joint during other stages of the case.* In considering the mechanical corrections of deformed joints, those still diseased are separated from those no longer diseased; and of the latter class which may and which may not be safely corrected without cutting operations other than *occasionally* subcutaneous tenotomies and myotomies.

Gall-Tract Infection

Dr. J. E. Coleman, Canton: The great number of unsuspected gall-stones found postmortem show that more care should be observed by the practitioner in the diagnosis of gall-tract infections, which always precede gall-stone and whose symptoms are always attributed to biliousness. Gall-tract infection is first a medical, then a surgical, then a medical disease, and should receive careful medical treatment before *and after operation*. The case should be referred to the surgeon for operation before adhesions and dangerous complications arise. This makes the operation a very safe one in competent hands. The diagnosis can be aided materially by close *observation* of the stools of the suspected patient and by watching for evidences of degenerative changes in the heart and blood vessels. The practitioner should see to it that the heart tone is fully restored after operation, and this usually requires *months of treatment*. The surgeon is often responsible for this not being done by his nihilistic attitude to medicine.

Persistent Infections in Specific Urethritis in Relation to the Penile Urethra

Dr. B. C. Corbus, Chicago: Persistent infections due to congenital abnormalities are common pathologic *conditions in* genitourinary surgery. Specific urethritis secondary to congenital malformations and localized *infections* (paraurethral abscess) form some of the most stubborn and persistent types of infections. Careful examinations by means of *the modern* methods now at our disposal will often reveal their presence. Early treatment based on the pathology of the condition *offers* the best method of eradicating the infection.

Discussion

Dr. L. B. Russell, Hoopeston: Every case of gonorrheal urethritis should be treated early if possible. When I *insert* the sound I leave it in for ten or fifteen minutes.

Dr. B. D. Baird, Galesburg: Gonorrhea, if neglected beyond a certain point, should almost be classified with the incurable diseases. The gonococcus was demonstrated in the urine in one of my cases seven years after the infection.

Dr. J. G. Fisher, Danville: I recall the case of a man who had had several attacks of specific urethritis. In July he had chills. I thought they were malarial and treated him for such, but quinin was of no value. By examining his urine I found a bacillus which resembled the colon bacillus. No culture tests were made, but according to the appearance and quantity, and its manner of conducting itself, it seemed to be an infection with the colon bacillus, and by putting him on urotropin the condition was somewhat cleared up. But I found this bacillus over quite a period of time following this, and finally his urethritis cleared up.

Dr. Corbus (closing): In regard to the value of antigonococcic serum and vaccine, the general consensus of opinion seems to be at the present time that they are valuable in systematic infection alone, not in local conditions.

Sympathetic Ophthalmia

Dr. E. V. L. Brown, Chicago: A characteristic infiltration of the iris, ciliary body and chorioid has been found to be constantly present in the first eye and consists of plasma cells. Transfer to the second eye does not take place along the optic nerves or by ciliary nerve irritation, but through the general circulation. The specific microorganism is first present in the general circulation and only becomes localized in the eye after the iris, ciliary body or chorioidea have been damaged by a wound or inflammation. It then first develops sufficient virility to attack the healthy chorioidea, etc., of the other eye. This endogenous theory is revolutionary in character, yet it better explains the peculiar localizations of the disease in the uvea and in certain parts of it than does the prevailing exogenous wound infection theory. The difficulties of diagnosis are great for general practitioners and for specialists alike. Syphilis and tuberculosis must be excluded. The prognosis is not invariably bad. Enucleation should help the second eye. Sodium salicylate in large doses, mercurial inunctions, etc., quiet the tissues, but no operations, no light and less atropin.

The Rationale of Infections of the Nasal Accessory Sinuses

Dr. W. L. Ballenger, Chicago: The etiology of infection and inflammation of the mucous membrane of the nasal accessory sinuses should be studied under two general headings—active causes and predisposing causes. The active cause is almost always a pathogenic microörganism, though in exceptional instances the condition may be due to traumatism, and external violence, caustics, hot irrigations, steam, irritating inhalations, etc. The predisposing causes are numerous, although an obstructed lesion of the nose, especially in chronic infection, is an almost constant factor. In primary acute sinusitis obstructive lesions are not so constantly present.

Early Efficient Surgical Treatment of Skull Fracture

Dr. F. C. Schurmeier, Elgin: Injuries of the head are never too insignificant for a most careful and painstaking examination. Where there is suspicion of intracranial trouble the patient should be kept under the eye of a competent observer. When the diagnosis of intracranial pressure is made operation should begin at once, if the seat of trouble is surgically accessible. It is never too late to operate, even though clinically it seems useless, and we fail in the attempt to save life. Operation should not stop short of efficiency when the patient's life threatens to cease.

Symptoms and Treatment of Exophthalmic Goiter

Dr. Cassius C. Rogers, Chicago: Goiter, tremor, tachycardia are usually present, but one or more may be absent. Other symptoms are mental disturbances, gastrointestinal disturbances, paralysis, impairment of vision, cardiac hypertrophy, cough, nephritis, sweating, etc. Special attention should be given to the female pelvic organs. I have not found an exception in exophthalmic goiter where the patient has not suffered with either amenorrhea, dysmenorrhea or menorrhagia. The ovaries are always large and tender. Not infrequently are these cases operated on and one or both ovaries removed. Invariably this is followed by a severe attack of acute exophthalmus. All acute cases should be considered as medical and never operated on until they have recovered, or until the disease has become chronic. Some cases apparently recover without treatment. There is no rule that can be followed in selecting the cases for operation. All acute cases and all cases with marked heart, liver and kidney changes are unfavorable for operation. The size of the goiter is not an index to the symptoms it may cause. Blood examination is of more value in acute than in chronic thyroidism.

The Study of Mental Disorders

Dr. H. Douglas Singer, Kankakee: The study of psychiatry has been evolving proportionately with the conception of mind. Psychologic factors play a large part in the etiology of insanity. Psychiatry presents its most hopeful outlook as a branch of preventive medicine. The promotion of this work by the study of psychological types of personality requires the cooperation of the medical profession as a whole. There is need of more extensive teaching, and especially of facilities for clinical study in the medical colleges.

Prevention and Treatment of Insanity

Dr. Eugene Cohn, Anna: There is urgent need of early treatment in all cases of insanity. It is best that the patient be at once placed in a proper institution. The general practitioner should be able to more readily detect insanity in its incipiency and should vigorously enforce the necessary measures for immediate treatment, for the sooner systematic treatment is begun the better are the chances for recovery. The existence of a sufficient number of psychopathic hospitals should be assured, where the sufferer may receive adequate treatment and observation prior to a formal commitment, by the court to a regular insane hospital or sanitarium. This final measure may not be necessary in many cases, and the patient is thus saved much possible embarrassment.

The Relations and Clinical Significance of Urinary Acidity

Dr. Henry R. Harrower, Chicago: The study of the urinary acidity and its relations is worthy of much wider attention. Its clinical significance is of importance in all disease conditions, but more especially in the definite and obscure chronic diseases. The acid index is a factor of considerably more importance than has yet been supposed and has an intimate relation with the phenomena commonly found with intestinal putrefaction and autotoxemia. The urinary acidity is not only of importance in diagnosis, but also serves as a valuable guide during the period of treatment. The frequent finding of evidences of kidney irritation would lead us to believe that the conditions causing urinary hyperacidity are important predisposing factors in the causation of nephritis. The test for the degree of acidity is simplicity itself and can be easily accomplished either with a burette or an acidimeter. The clinical indications and therapeutic possibilities suggested by these findings will more than repay one for the slight trouble required in making the tests.

A Practical Measure in the Prophylaxis of Postoperative Cystitis

Dr. E. C. Dudley, Chicago: During the past two or three years in all cases in which the catheter was used I have followed its use with the instillation of boric acid and argyrol solution. Whenever I have especially anticipated postoperative cystitis I have had the catheter passed at stated intervals and the boric acid and argyrol solutions used. This tentative catheterization may be quite essential since pelvic operations are apt to be followed by partial retention, and since partially retained urine is especially apt to give rise to cystitis. After perineorrhaphy, for example, the rule that the catheter should be avoided when the patient can relieve herself holds good only when natural urination is complete. Since I have applied the routine treatment of postoperative cystitis to the prophylaxis of cystitis, I have observed freedom from infection, and corresponding relief from a frequent distressing and humiliating sequel to pelvic surgery. The results are fully as satisfactory as are those following the application of a silver solution to the eyes of the new-born.

AMERICAN NEUROLOGICAL ASSOCIATION

Thirty-sixth Annual Meeting, held in Washington, D. C., May 2-4, 1910

The President, DR. MORTON PRINCE, Boston, in the Chair

Cerebral Localization from the Point of View of Function and Symptoms, with Special Reference to v. Monakow's Theory of Diaschisis

DR. MORTON PRINCE, Boston: The doctrine of cerebral localization resolves itself into the question whether the localization is of symptoms or of function or whether it is only an anatomic localization of fibers. It too often happens that the formulas of localization do not work in diagnosis. It not rarely happens that clinical and pathologic findings are contradictory. Thus, on the one hand, extensive lesions in one or other of the recognized cortical centers run their course without symptoms, and, on the other hand, focal symptoms, pointing to disease of these centers, develop in cases in which no anatomic alterations are found at autopsy. There is growing dissatisfaction with the currently accepted doctrine of cerebral localization; a feeling that it is in many respects inadequate. The first blow to the traditional localization of function in the cortex was received when Marie launched his attack on the doctrine of aphasia. Whatever the outcome of the reinvestigation of this question shall prove to be, it is evident that the beautifully diagrammatic conceps of the function of language and of aphasic disturbances of this function have been relegated to the scrap heap of the phantasies of science. The fact, I believe, will be found to be that whether the third left frontal convolution, the first and second left temporal convolution or other areas take part in the function of language or not, the function as a whole, as a psychical process, is a widely distributed one in which are engaged many dynamic processes and anatomic "centers," and a lesion of any one of several "centers" may give rise to all modes of aphasic disturbance. The contest has centered largely around the question whether a lesion of Broca's convolution gives rise to the motor type of aphasia and, therefore, whether in this convolution can be localized so much of the language as is lost in this type.

The clinicoanatomic data themselves are contradictory; as. for example: 1. Lesions of the third frontal convolution do give rise to a clinical aphasic syndrome of the so-called motor type. 2. Destruction of Broca's convolution may be accompanied by simple mutism—or pure motor aphasia of the so-called subcortical type. 3. It also appears to be true that in a considerable proportion of cases of aphasia, characterized by loss of the power of word formation and articulation, Broca's convolution has been found intact. In any theory of aphasia as a clinical syndrome, and in any theory of function these discrepancies must be reconciled. Von Monakow, whose clinical experience and pathologic training entitle his views to great weight, points out the inadequacy of the generally accepted doctrine of localization to account for these contradictory phenomena. He believes that there lies some error in the form in which localization is conceived by most clinicians. To-day, as formerly, two sets of experiences stand opposed to one another—the negative and the positive—and invite anew discussion of the doctrine of localization, which has been declared closed by many writers. How can these contradictions be explained? To answer this von Monakow proposes a theory, which is of the greatest interest and challenges examination, known as diaschisis, and which has for its basis the results of experimental investigations. After removal of focal areas in the cortex, certain symptoms are temporary, while others, which are purely local, are permanent. These latter, or residual, symptoms alone represent the function or part of function that is localizable in a given center. So-called focal symptoms are in large part a complicated reaction of unimpaired areas of the central nervous system to the local cortical lesions. By diaschisis is meant a functional, shock-like inhibition of previously uninjured distant areas produced by the dynamic influences of a lesion anatomically connected with such areas. Through the break in the continuity of the conducting associative paths the eccentrically lying brain foci are robbed of their natural sources of stimulation and in part isolated. Only the directly injured elements give rise to the permanent symptoms and secondary degenerations. So far as the theory definitely distinguishes between the localization of symptoms and the localization of function, I think it may be safely insisted on as the only interpretation that can reconcile the facts of clinical and pathologic observation. The diaschisis theory is fruitful in other fields than that of cerebral localization. For example, its possible applications in the explanation of focal symptoms without focal lesions will occur to everyone.

A Report of Three Prefrontal Tumors

DR. F. X. DERCUM, Philadelphia: In the first and second cases, the tumors were inoperable; the third tumor was removed, but was of enormous size, weighing 7¾ ounces. Death occurred 14 days after operation. The symptoms present in the reported cases are of unusual interest. Vague mental symptoms were present in all. Case 1 suggested symptoms not unlike those of profound cerebral exhaustion of a beginning paresis. Headache had never been a marked feature and was elicited only by questioning. It existed only for a short time previous to death; vomiting occurred but once, and that only toward the very close of the illness. There was absence of optic neuritis and any involvement of the visual fields. The only symptom which was at all suggestive was one attack of slight twitching of the left leg and possibly twitching of the left arm which occurred a few days before the patient came under observation; the attack was very brief in duration and was not attended by loss of consciousness. Occasionally psychic vesical incontinence was present. In the second case there was early headache, optic neuritis and vomiting, all the symptoms being typical and marked. The feature of special interest was the slight flattening of the lower half of the right side of the face and the equally slight involvement of the left leg and arm. These symptoms were in all probability due in part at least to indirect pressure. The subjective sensory disturbances, namely pain and the hypesthesia of the left arm and both legs, are somewhat difficult to explain. The occurrence of typical areas of hysterical painful hyperesthesia under both breasts and over both groins must be borne in mind in considering the other sensory symptoms present. The area of hyperesthesia on the left parietal region was also small and resembled in other respects an area of hysterical hyperesthesia, though it was present on the same side as the tumor. The question arises: Was the left hemiparesis, present for a time only, also hysterical in origin?

In Case 3 optic neuritis was pronounced. Headache was scarcely, if at all, present. Vomiting was absent. This case is remarkable for the size of the growth which had probably existed for a long time previous to the seizure which occurred in the summer of 1908. That so large a growth could have been present and the patient still have been able even in a degree to attend to business and ordinary affairs is very remarkable. Finally, the resemblance of the mental symptoms in Cases 1 and 3 to those of paresis is worthy of comment. In Case 1 the patient was placid, indifferent, and did not manifest the least anxiety as to his condition. In Case 3 the patient was at times distinctly expansive, good-humored and not infrequently laughed and joked. In Case 2 the patient, though quiet, complained greatly at times of suffering; at no time was she jocose nor was there any tendency to laughter or hilarity. Indifference to the sphincters was not observed and there were no epileptiform seizures. The eye muscle symptoms made their appearance late and are probably to be referred directly to the frontal lobe lesion; in part they may have been due to the blindness and the absence of fixation. In many respects these cases conformed to the ordinary observations made in prefrontal tumors. This was particularly the case as regards the mental symptoms which were most marked in Case 3, less marked in Case 1 and least in Case 2. Psychic incontinence was pronounced in Cases 1 and 3. Epileptiform seizures were present but once in Cases 1 and 3 and absent altogether in Case 2. Optic neuritis was present in Cases 2 and 3 and absent in Case 1; the swelling was more marked on the side of the tumor in Case 2 and slightly greater on the side opposite the tumor in Case 3. Local tenderness of the skull was present only in Case 2; was on the same side as the tumor but was parietal and not frontal. Finally, it is interesting to note that in none of the cases was there any ataxia.

It should be added that no x-ray examination was made in Case 1. In Case 2 an x-ray examination was negative. In Case 3 an x-ray examination was also negative, save that it revealed some irregularity of the inner surface of the frontal bone on the right side, and also some apparent thinning of the bone. The possible etiologic value of trauma is well illustrated in Case 1.

DISCUSSION

DR. E. W. TAYLOR, Boston: The two main points brought out are interesting. In the first place the mental condition; in the second place the epileptiform seizure. I presume it is generaly accepted that there is no definite type of mental disease to reveal frontal lobe lesion. I recall distinctly a patient in whom the mental symptoms, instead of being apathetic, were precisely the opposite. The man was a young army officer, previously healthy. He was extraordinarily apprehensive; he developed all sorts of phobias, was unable to go into crowded places, buildings and so on, and presented all the appearances of a mental state. He had slight epileptiform convulsions, which I misinterpreted as hysteroid convulsions. He disappeared from view, and if I had not heard his subsequent history I would have regarded him as a psychasthenic patient. He later came under treatment and died. Autopsy revealed an extensive prefrontal tumor, gliomatous in type, very difficult to distinguish from the brain itself. The points of importance are incidence of slight seizure, epileptiform in character, and, secondly, and still more confusing, are the phenomena one so often sees in the neuroses of psychasthenic character.

DR. EDWARD B. ANGELL, Rochester, N. Y.: I have been impressed with the lack of symptomatology of prefrontal tumors. Many of these patients are without headache, nausea, vomiting or any of the motor symptoms, and without any of the hemiplegias or disturbances of one side of the body. The case of a very successful and intelligent business man came under my observation a year ago. He suddenly became apathetic; his family first noticed this because he received news of a disaster with unconcern. Aside from that condition he had no symptoms whatever. He had an attack of influenza and had quite a nasal discharge and an increase in the white blood cells. Here was a case where there was reason for suspecting acute trouble by extension from the nasal chambers. The mental symptoms were not such as to indicate much pressure. When the man died, and it was shortly, it was found that he had a tumor as large as that of Dr. Dercum's patient in the left prefrontal lobe.

DR. HUGH T. PATRICK, Chicago: What was the state of the sense of smell in these cases?

DR. HERMAN H. HOPPE, Cincinnati: I wish to refer to a symptom-complex which obscured the diagnosis in a case in which there were absolutely no general symptoms of brain tumor. The tumor grew from the sella turcica and involved both portions of the frontal lobes. The earliest manifestations were in reference to the optic thalamus. This man went on with business after developing atrophy of the optic nerve; then he began to develop sluggishness of the pupils. In the subsequent history there was a pure simple dementia, so much so that the diagnosis of dementia paralytica was made. The man died in the insane hospital and autopsy revealed the tumor.

DR. GEORGE JACOBY, New York City: I saw the patient in the case reported by Dr. Dercum and, after seeing and comparing it with two others I had previously seen, it seems to me that we can be very positive that there is no pathognomonic series of symptoms of prefrontal tumors. One way in which diagnosis can be made is by sequence of symptoms or symptoms dependent on pressure. The occurrence of aphasia and involvement of the motor tract and the significance of reflexes are also helpful and indicative of the associated pressure.

DR. E. E. SOUTHARD, Boston: I have found that in some cases it is profitable to examine histologically other parts of the brain than those directly involved in the tumor. I recall a case of tumor of the prefrontal lobe in which epilepsy did not exist but in which there was a unilateral paralysis on the same side as the tumor, and histological study of the precentral gyri showed that for some reason on the opposite side there was absence of cells.

DR. B. SACHS, New York City: I do not know why these tumors are spoken of as prefrontal tumors. There are two points of vital importance in regard to the question of operability. The focal signs in many instances give no idea of the actual size of the tumor and the probable result of an operation. So much depends on shock, which seems to be in direct proportion to the size of the tumor, that one of the most essential points for determining the operability of a tumor is to try to decide whether the tumor is of large size or not and whether the symptoms give one any idea of the size of the tumor. The other points belong to all tumors. A great deal depends on the character of the tumor, particularly in the development of symptoms. There is a great difference in conditions when the brain substance is being invaded by tubercle or sarcoma or when it is being gradually invaded by a glioma; and some of the peculiarities in regard to tumor of the frontal lobe may be explained by the fact that many of these tumors have been slowly invading gliomata, whereas the cases in which the tumor has been much more destructive the symptoms are more marked. The destructiveness of the tumor is in direct relation to the distinctness of the symptoms. I observed a case which had presented during life absolutely nothing else but epileptiform seizures, in which the patient suddenly died from hemorrhage from a tumor which on postmortem examination proved to be a huge glioma involving the entire one hemisphere of the brain. A point we often lose sight of is the different character of the symptoms in relation to different structure of the tumor. Glioma seems to cause fewer symptoms than any other tumor because the brain tissue accommodates itself much more readily to the slow invasion of the glioma.

DR. D. D. WOLFSTEIN, Cincinnati: I wish to refer to a case in which I made the diagnosis of tumor of the frontal lobe. It was in the left frontal lobe and of very large size, but there was absolutely no mental disturbance. The only symptoms were progressive optic atrophy with complete loss of vision. There was a suspicion of epileptiform seizure. Very often these tumors pass far back and tangential fibers which pass through the capsule are involved. Those cases which simulate epileptiform seizures might in this way be explained.

DR. F. X. DERCUM, Philadelphia: In these cases the sense of smell was preserved. In a case which I reported to this association some years ago the sense of smell was destroyed. I think Dr. Southard's position well taken. It seems to me that the epileptiform attacks in these cases were perhaps due to pressure about the base. I am in entire accord with Dr. Sachs' statement in reference to the size of the tumor. The first two cases were round-celled sarcomata; the third was endotheliomata and sprang from the dura of the base. I feel that the term "prefrontal" is justifiable, provided we mean that the tumor has advanced up in front of the motor tract itself.

OHIO STATE MEDICAL ASSOCIATION

Sixty-fifth Annual Meeting, held at Toledo, May 11-13, 1910

(Continued from page 1809)

Femoral Hernia

DR. GEORGE F. GOODHUE, Dayton: Congenital femoral hernia is unknown. Before the age of 20 it is exceptional, and in children it is a rarity. A consideration of the anatomic conditions involved in this hernia would lead us to infer that its production must be caused by prolonged strain or violent exertion far beyond the ordinary. The connective tissue sheath enveloping the vessels is strong and unyielding in the young and healthy, which explains its greater prevalence in the weak and aged or those exposed to unusual strain in their daily avocations. The greater size of the canal in women, and the firmer character of the inguinal ring in that sex renders this variety of hernia more common in the female. My method of operating for the relief of this condition, which I believe the safer for the average surgeon, closely conforms to that of Bassini, which consists in fastening Poupart's ligament to the pectineal fascia and muscle and sometimes the falsiform ligament to the same structure by catgut sutures. I wish to emphasize the statement made by Ferguson, that in every case of femoral hernia except in extreme old age or infirmity the patient should be subjected to operation for radical cure. This advice is based on the extreme danger of strangulation in this variety of hernia which much sooner become gangrenous owing to the tense, firm sharp border of the ring. This risk to life must never be under-estimated. Trusses—barbarous in every variety—are rarely efficient in this form of hernia. The operation is fraught with little danger and in the hands of experienced surgeons under proper conditions success is assured.

DISCUSSION

Dr. F. F. Lawrence, Columbus: When strangulation occurs it would be well to consider the possibility of the bladder being engaged in the hernia mass, and to recognize what the hernia contains would be important. It has been my practice to expose the sac, tie it off and drop it, and then try to approximate Poupart's ligament either to the pectineal muscle or fascia, thereby making the space on the side of the femoral vein much smaller.

Dr. R. B. Hall, Cincinnati: Of all varieties of hernia the physician is called on to treat the femoral hernia requires most prompt action, for with strangulation the tissues in the sac may become gangrenous in six hours. In one case the vermiform appendix was found in the sac on operation. Recurrence of the hernia would be rare if the technic advocated by Dr. Goodhue were followed out.

Dr. G. F. Goodhue: It is necessary to note the natural course of a descending femoral hernia in order to succeed in reducing the hernia by taxis. I do not think taxis is the proper measure to resort to, except as a temporary expedient, as when the case is seen in emergency or before transporting the patient to a hospital. Another point I wish to emphasize is the desirability of introducing the stitches through the pectineal muscle and fascia well down on the pubic bone, so that the ligament is brought well down over the surface of the muscle and fascia instead of just having the edges approximated.

Instruments Used and Points of Technic of the Major Smith Cataract Operation

Dr. D. T. Vail, Cincinnati, gave a detailed description of each instrument Smith uses in his operation, and related the arguments he presents to prove the advantages of each of these instruments over any other pattern in common use. He also exhibited a complete set of instruments, original and not original, which Smith uses in doing the operation, and gave arguments to prove that these simple instruments meet all the demands which arise in every operation for cataract, whether in or out of the capsule. He mentioned the dangers that an operator invites who attempts to extract cataracts in their capsules by the employment of the ordinary set of instruments, and sounded a note of warning to those who would exercise the courage to undertake the Smith operation, so-called, as a routine practice without thorough knowledge and appreciation of the principles which underlie successful extraction in the capsule.

Prognosis in the Traumatic Neuroses

Dr. Louis Miller, Toledo: There are few diseases which have received more attention concerning their prognosis than the wide group of diseases known as the traumatic neuroses; although specialists have been more or less at variance in their opinions on the subject, yet not so much so as general practitioners and often other members of the profession. This is especially true of those cases which are the subjects of litigation. While much of the disagreement may be placed to the blame of the prejudice attending taking sides with the parties in cases, which are the subjects of litigation, all cannot be thus explained. The difficulty lies partly in the inherent complexities of the conditions with which they have to deal, such as exact diagnosis; partly to the confusions of nomenclature. In recent years authors are coming closer together in their views of prognosis, but one still reads opinions which give impressions considerably at variance. In the term traumatic neuroses I include only functional disorders resulting from violence, *i. e.*, hysteria and neurasthenia and states which cannot be separated clinically from them. The disorder has been designated as accident aboulia, traumatic hysteria, traumatic neurasthenia, and other terms, but traumatic neurosis is comprehensive and will probably lead to less confusion if adhered to universally. Admitting then that these neuroses do not constitute a distinct disease entity, but are either neurasthenia or hysteria, or a combination of them, we can say in general that the prognosis is that of those two affections.

Malingering and Its Detection

Dr. E. E. Gaver, Columbus: It is in the field of psychiatry or neurology that we encounter the majority of cases of malingering. Malingering is divided into three varieties—exaggeration, substitution and entire simulation. Exaggeration of disease is the most common endeavor, and is usually found in the functional diseases, such as hysteria and neurasthenia. In the organic diseases there is sufficient pain without additions or exaggeration. The substitution of origin of a disease is difficult to detect in a well-trained criminal. Physical defects form a prominent basis for fraudulent substitution of origin. A defective eye, a scar on the head or neck, or defective hearing commonly form the basis for claims. Entire simulation is the real true form of malingering and is the comparatively rare form. Very few attempts to defraud by such means are now successful. Physicians are most concerned in the detection of malingering. The symptoms in nervous diseases most commonly feigned are disturbances of vision and hearing, anesthesia, convulsions, contractions, paralysis, tremors, disturbances of gait, pain and hyperesthesia. The visual malingerer is usually turned over to the ophthalmologist for detection. An ordinary stethoscope is a useful adjunct in detecting any fraud in the claim of deafness. By connecting the stethoscope, either branch of which can be separated at the will of the examiner, in the ears of the patient and operating from behind it is usually a simple matter to conduct sound to either ear singly or simultaneously and with ordinary cleverness in manipulation the operator will reveal hearing in both ears if it really exists. In testing for feigned loss of sensation we must bear in mind the fact that most individuals can nerve themselves to the point of withstanding extreme pain. Defeat, however, is almost certain to follow the unexpected application of painful stimuli, such as the faradic current or some sharp instrument.

It is usually in an effort to play the part of an epileptic that convulsions are feigned. An examination of the subject, if he is a malingerer, will not reveal the scarred tongue and head the result of injury, the pupils will continue to react, and the reflexes are not lost. Paralysis is one of the most common symptoms simulated. Paralysis is usually accompanied by atrophy, changes in the reflexes, electrical reaction of degeneration, vasomotor disturbances. The simulation of tremor is difficult and should be fairly easily detected. A useful test is to place the subject on the belly, and if he can press his toes on the bedding the tremor can be maintained, but should the legs be flexed at the knees the tremor ceases. The more irregular a tremor the less possibility of its being real. There is no known means of determining whether a pain is real or fraudulent. Judgment must be passed on weight of evidence afforded by accompanying symptoms or signs. Continued severe pain soon impairs nutrition and sleep. According to some authorities, pressure over a tender area will increase the pulse rate often as much as 20 beats a minute and in some instances it produces sweating. Disturbances of gait usually carry with them other signs impossible to simulate.

"Pole Ligation" for Exophthalmic Goiter

Dr. J. H. Jacobson, Toledo: In a preliminary report on this method made in October, 1909, I formulated the following conclusions:

1. Ligation of both poles of the thyroid acts first by diminishing the blood supply to the gland, and thus diminishing immediately its activity; secondly, by directly diminishing and preventing the gland secretion from entering the general circulation by way of

the main lymphatic channels and veins which leave the thyroid body at its upper poles; and thirdly, by causing a subsequent atrophy of the gland itself.

2. The pole ligation is much easier to perform than ligation of the thyroid vessels, and may be as effective as a partial thyroidectomy.

3. It does not disturb the blood supply of the parathyroid glands, nor endanger the recurrent laryngeal nerves.

4. Theoretically, at least, and from the simplicity of its performance, it would seem that pole ligation should entirely supplant the operation of simple ligation of the thyroid vessels in Basedow's disease, and in many cases the necessity of partial thyroidectomy.

5. As a preliminary operation to partial thyroidectomy for Basedow's disease it will be found of great value.

6. At present, we are warranted in saying that pole ligation offers the prospect of cure in many cases, and of lasting improvement in others.

7. The operation of pole ligation is a safe one, and in skilled hands should have no mortality.

Subsequent experience with this operation has shown these conclusions to be correct. Theoretically at least it seems that the ligatures should be placed extracapsular, for the reason that the lymphatic vessels of the gland parenchyma empty into those contained within the capsule and that the extracapsular ligature will more effectually stop the gland excretion. We are confronted by many difficulties in estimating the effect or value of any operation for the relief of this disease, particularly as to what constitutes a cure in these cases. All these patients are improved by the operations of partial thyroidectomy, ligation of arteries, or pole ligation. In only a very small number do all the symptoms entirely disappear. It is obvious that the same conditions confront us in estimating the end-results of partial thyroidectomy.

DISCUSSION

DR. JAMES DONNELLY, Toledo: In making the double ligature one can notice, when tying it, that there is immediately a blanching of the gland, showing that there has been considerable decrease in the quantity of blood sent to it. Dr. George W. Crile has shown that the nerve connection has been an element in the successful treatment of the condition.

DR. S. J. FOSTER: While ligation of the artery is theoretically easy, yet at times it has been found very difficult, and the operation now advocated of extracapsular ligation is a distinct advance, because of its ease of execution. Besides, there is practically no mortality and the end-results of the operation promise a great deal.

DR. J. H. JACOBSON: The exact distribution of nerves to the thyroid gland is not known, but reasoning by analogy is the same as in other portions of the body, so that in putting a ligature around the pole, we get the arteries, veins, nerves and lymphatics. I think the lymphatics are the most important. It has been shown that the thyroid secretion gets into the circulation through the lymphatic glands. In many of these cases the lymphatics are found to be enlarged at operation. Cross-section of the glands shows a deposit in them of colloid material.

Pneumonia with Severe Abdominal Symptoms Simulating Acute Disease of the Region

DR. H. J. WHITACRE, Cincinnati: A review of the literature on this subject shows that the condition is by no means infrequent. Surgeons of wide experience and unquestioned ability have committed the error of operating on the abdomen, and the error is at times unavoidable. An incomplete history and physical examination as a rule will be the direct explanation of most errors. These cases usually arise as grave emergencies. The surgeon is called for an acute appendicitis—he finds a history of sudden onset with severe pain and vomiting, an elevation of pulse and temperature, the right rectus rigid, and he neglects all further examination of the patient. There are certain points which will be of value in the diagnosis: (1) The countenance of the patient will not be peritonitic, and there is apt to be some grade of cyanosis; (2) the tongue is moist and not coated; (3) respiration is frequent, out of all proportion to the pulse rate, and costal in type—there is often a definite catch at the end of inspiration; (4) abdominal rigidity is less circumscribed than in appendicitis and is very great—the abdominal wall relaxes for a moment with each inspiration; (5) abdominal sensitiveness may be local, unilateral or general, but is always superficial, deep pressure is not painful; (6) a sudden high temperature (continuous) has been observed very frequently, which is not true in appendicitis; (7) a careful objective examination of all organs is most necessary. The explanation of the abdominal symptoms is not clear. In many cases it seems most probable that the pain, sensitiveness and rigidity are to be explained by an irritation in continuity of the lower six dorsal nerves. Irritation of the seventh, eighth and ninth nerves will cause pain in the epigastrium, and will simulate gall-bladder disease or ulcer of the stomach, while irritation of the tenth and eleventh nerves will cause signs in the appendix region. In other cases, the sensations are purely reflex and result from irritation originating in the lung, which are transmitted either through the costal group or through the vagus to produce visceral pains. The intestinal paralysis which has been prominent in many cases has been explained by some as the result of toxemia; by others, as a reflex disturbance of the splanchnic system.

Prostatectomy

DR. W. D. HAMILTON, Columbus: Experience gives us great confidence in the perineal operation, while for some cases in which the gland has developed considerably at the expense of the intravesical space, so that it may be more accessible from above, the high operation is occasionally of great service. The low operation is anatomically more difficult in the average case, and may be followed by several conditions which may be regarded as unfortunate results: (1) incontinence of urine; (2) stricture of the urethra; (3) urethrorectal fistula; (4) damage to the sexual function; (5) fistula. My first report contained a tabulated list of seventeen patients on whom prostatectomy had been done with 4 deaths. Since the publication of that paper, the operation has been done 43 times in the practice of Dr. Charles S. Hamilton and myself. Of the 43 cases, 9 were for malignant disease, and 34 for benign lesions. Of the malignant cases 8 were adenocarcinoma, and 1 of round-cell sarcoma; of the 9 patients, 3 died, and 6 recovered. Of the 34 benign cases, 4 patients now in the hospital are at various stages in their apparent convalescence. Of the 30 operated on for benign lesions, 3 have died and 27 recovered. This would make a mortality in this latter series, and covering the benign cases only, of 10 per cent. Of the 34 cases it may be of interest to observe that 26 of them were adenofibromata.

EMPLOYERS' LIABILITY AND WORKMEN'S COMPENSATION LAWS IN THE UNITED STATES

By Chauncey Rea Burr, M.D.
PORTLAND, ME.

Under the title of "The Federal Compensation Act of 1909," a measure is before Congress which, if passed, will go far to remove our reproach among nations for the indifference with which hitherto we have treated our injured workmen.

It is remarkable that up to the present time no demand loud enough to be heeded has come from the workingman to indemnify his dependents in case of his own death from accident occurring in the line of his employment, or to pension him for permanent disability.

The empire builder, Prince Bismarck, appreciated the worth of the human machine and provided statutory enactment to pay for it when damaged or destroyed. Incidentally he dealt the socialist cause in Germany the hardest blow it has ever had. In the earlier part of the Nineteenth Century the right of the workmen to redress from accident was that of anyone else, viz.: in order to recover damages, he must prove default on the part of the person who injured him. To prove default on the part of the employer or his agents was often a difficult if not impossible matter even when this was known to exist. The explosion of a steam boiler might not only kill all the witnesses to the accident, but might so alter the surrounding as to render it impossible to secure evidence as to the cause. The industrial expansion of the Nineteenth Century, with a corresponding increase of industrial accidents, and an increase of killed and maimed workmen, swelled the ranks of the destitute and added to the misery and discontent of the submerged classes. Hence it became a matter for the government to investigate. Between the years 1883 and 1900 a series of laws was passed in Germany providing for indemnity against disease, accident or death among workmen; such indemnity to be paid by an assurance society whose solvency was secured by legislation. In 1883 a law for compulsory insurance against loss of wages from sickness was passed, one-third of the cost to be borne by the employers and two-thirds by the workmen. In 1884 a similar law against loss of wages from accident was passed. Five supplementary laws followed and in 1900 all were grouped under one law, which placed the whole burden of compensation for accident on the employer.

In 1889 a law was passed providing for pensions for old age and invalidism, the cost of which was divided between the state, the employer and the employee. The classes who benefit by this insurance are limited to those employed in mines, salt works, quarries, smelters, factories, railways, steamboats, agricultural operations, lumbering and forestry, building trades, breweries, warehouses, butchering, well digging, domestic service, and also seamen, longshoremen, blacksmith, locksmiths, chimney-sweeps and window cleaners. Such persons injured during their work are entitled to free medical treatment, medicine, sick-pay (i. e., two-thirds of the daily wages) and hospital care, if necessary, for a period of thirteen weeks. With the beginning of the fourteenth week the case comes under the care of the "Trade Association," composed of employers and employees engaged in the same industry, which fixes the amount of the indemnity. This varies with the disability. If total, the full amount of the yearly wage is paid as a pension in monthly instalments; if partial, a proportionate amount only is paid, as high, it may be, as two-thirds. Fraud is guarded against by compelling each pensioner to be examined by the trade association physician every six months. Thus pensions may be increased or diminished or stopped altogether, as the condition of the recipient warrants. Should the workman be killed as the result of the accident, the widow, if there is one, is entitled to burial expenses, and twenty per cent. of her late husband's yearly wage during her widowhood. If she remarries she receives a lump sum of sixty per cent. of the yearly wage in full discharge. Each minor child of the deceased is entitled to twenty per cent. of his father's yearly wage till the age of fifteen years; and dependent parents or grandparents are entitled to the same twenty per cent. pension *per capita.*

These laws have proved to be the prototype of most of the European legislation on employers' liability and workmen's compensation, which has been enacted in recent years. Thus Austria legislated on the subject in 1887 and 1888; Norway in 1894, 1897 and 1899; Finland in 1895; Great Britain in 1897 and 1908; Denmark in 1897; Italy in 1898 and 1903: France in 1898 and 1902; Spain in 1900; Greece in 1901; Sweden in 1901; Russia in 1904; Belgium in 1903. One or the other of two principles runs through this legislation. The first may be defined as the principle of the personal liability of the employer to his workman; the second, as the principle of compulsory insurance. Sometimes an attempt is made to combine the two.

In 1908 the United States made her first essay into the field of workmen's compensation for accident. May 30, 1908, an act was passed "granting to certain employees of the United States the right to receive from it compensation for injuries sustained in the course of their employment." The persons eligible under this act are such as are "employed by the United States as artisans or laborers in any of its manufacturing establishments, arsenals or navy yards, or in the construction of river and harbor or fortification work, or in hazardous employment or construction work in the reclamation of arid lands or the management and control of the same, or in hazardous employment under the Isthmian Canal Commission." If such persons die as the result of an accident received in the course of their employment, their dependents shall be entitled to receive for the remainder of the year the same amount that the deceased would have received as wages for the same period.

If the employee shall be "injured in the course of such employment," he shall be entitled to receive for one year thereafter, unless in the opinion of the Secretary of Commerce and Labor he be able to resume work sooner, the same pay as if he had continued to be employed. No payment to be made, if the injury is due to the negligence or misconduct of the employee, nor unless the disability continues for more than fifteen days. Provision is also made for a medical examination of the injured employee at least once in six months, by order of the Secretary of Commerce and Labor.

In this act no distinction is made between partial and total disability. Defective as this law is, it was apparently the opening wedge for more comprehensive legislation. Feb. 10, 1908, a bill "to provide compensation for injuries to employees solely engaged in interstate and foreign commerce, to which the regulative power of Congress extends" was introduced in the House of Representatives by Hon. Adolph J. Sabbath of Illinois. In introducing his bill Mr. Sabbath said: "In the course of an experience of over twelve years on the bench in Chicago, one of the greatest cities in the world, every kind and class of cases were brought before me. My duty not only consisted in enforcing the laws, but in attempting to alleviate the misery and the damages caused by our modern economic system. This last function was impressed on me by the horrible cases of breaking up of families, degradation of the widows and ruin of the daughters, caused by the loss of the father's or brother's earning power. Years and years of litigation, appeals, new trials and all the necessary steps of our modern procedure brought it about that the results of the litigation were wasted; and social degradation of the family, without any fault of their own, ensued. . . . The object of my compensation bill, as of all compensation acts, is to correct what heretofore has amounted to a denial of justice." This bill failed of passage, and on March 15, 1909, Mr. Sabbath introduced a somewhat different measure, entitled, "A bill to require persons carrying on occupations and trades subject to the regulative power of Congress to pay compensation to employees injured, and to change the general law for injuries received on mail routes." This bill, the federal compensation act of 1909, which it is the object of this paper to describe, applies only to the employees of common carriers engaged in interstate and foreign commerce or in transporting the mails, which are subject to the regulative power of Congress. Such common carriers include steam railroads, electric roads, and vessels which convey the mails, express companies and sleeping-car companies operated on a mail route. Whenever the employee of such a common carrier is injured, the latter shall pay the former compensation without requiring an action at law to be brought. The amount of compensation is governed by a schedule annexed to and made a part of the act.

For the purpose of carrying into effect the provisions of the act a commission to consist of three members is established, to be known as the "Federal Commission of Injury Awards." The principal office is to be at Washington, although "whenever the convenience of the parties may be promoted or delay or expense prevented thereby, the commission may hold its sessions in any part of the United States." When an employee is injured or killed, the common carrier must notify the commission, and this in turn notifies the employee or his widow or next of kin of their right to compensation. It then remains for the employee, his widow or next of kin to decide whether they will accept compensation under this act or bring suit for personal damages. It is further provided that in any future contracts with common carriers for forwarding the mails, the Postmaster General is forbidden to sign such till the common carriers agree to the indemnity stipulations.

The schedule of injury awards is as follows: For death due to injury in the course of his employment the employee's widow or dependent next of kin is entitled to an annual pension of seventy per cent. of the deceased's monthly wages, during their life or while they are entitled thereto; i. e., a widow forfeits her pension by remarriage, or a minor child on reaching a working age. If there is no widow or dependent next of kin, then only the medical, surgical and burial expenses shall be paid. No disability shall be paid for which does not exceed two weeks. For total disability not exceeding six months there shall be paid one-half of the monthly wages for that period, as well as hospital, surgical and medical attendance. For total disability continuing after six months, there shall be paid two-thirds of the weekly wage during the period of said impairment. When the earning capacity is materially impaired through partial disability, one-half of the weekly wage is to be paid. When the earning capacity is slightly impaired, through partial disability, one-fourth of the weekly wage is to be paid; provided that such disability is not covered in the following scale of percentage awards.

The scale referred to deals with the loss or total impairment of certain parts of the body and follows very closely the order given in "Instructions to Examining Surgeons" issued by the Bureau of Pensions, Washington, D. C. The awards, however, are not the same, although in many cases approximate. On the whole they are larger. The scale is too long to give in full, but enough follows to give an idea of its scope. The figures show the percentage of the earnings which will be paid as an annual pension for the stated disability.

SCHEDULE OF AWARDS

Loss of one eye, 40 per cent.; loss of hand, 40; loss of foot, 40 to 50; loss of an arm at or above the elbow or a leg at or above the knee, 45 to 60; loss of either a leg at the hip-joint or of an arm at the shoulder-joint, or so near as to prevent the use of an artificial limb, 40 to 60; loss of thumb, 20; loss of index finger, 06; loss of great toe, 08; ankylosis of shoulder, 30; ankylosis of elbow or knee, 25; ankylosis of ankle or wrist, 20; total deafness of one ear, 25; hernia, 20 to 50.

A distinction is made between the right hand and the left as to their respective values. Thus, "loss of thumb, index, middle and ring fingers" is rated at 25 per cent.; while "loss of thumb, index, middle and ring fingers of right hand" is rated at 40. The difference in value between a right and left hand can only be in a difference of skill between the two, for very few persons are ambidextrous. If therefore a skilled workman who is right-handed, loses his right hand, he loses something more than the hand. He loses skill, the ability to compete with his fellows, the power of earning the same pay. There is in short a loss of competing power as well as a loss of physical power. Everybody recognizes this where the hands are concerned, but it is not so easy to realize when the injury is internal and out of sight. In a given case these separate elements of damage ought to be considered and rated separately before a just estimate of the total damage to the earning power can be arrived at. The bill, however, while not entering in detail on this more extended field, very cleverly covers it by providing one rate when the earning capacity is "materially impaired" and another when it is but "slightly impaired." These are vague terms, but the award is not. On the whole the bill leaves but little to be desired, and Mr. Sabbath is to be congratulated on the masterly way in which he has grappled with the problem, and it is to be hoped that Congress will think likewise and enact the bill into law.

In the last analysis the public will pay the cost of these pensions in increased freight charges or mileage, but it is worth it. As the government pays pensions to its soldiers and sailors and certain of its civil employees, and by this bill, if passed, the railroads to their employees, it is unfair that workmen in general should not under like circumstances have pensions paid them. Perhaps in time this will come here as it has in Germany through the medium of "trade associations." For the purpose of comparison, the following table is appended, which shows what the various nations have done in the way of pensioning their disabled workmen.

TABLE SHOWING THE ACTION OF VARIOUS NATIONS IN THE WAY OF PENSIONING DISABLED WORKMEN

Country.	Total and permanent disability.	Partial and permanent disability.
Germany	An annual pension equal to the full amount of the yearly wage.	Proportionate pension up to two-thirds of yearly wage.
Austria	An annual pension of 0.60 of yearly wage.	A pension of not more than 0.50 of yearly wage.
Norway	An annual pension of about $41.50.	Proportionate pension, but none unless earning power is diminished at least 0.05.
Great Britian.	An annual pension of 0.50 of yearly wage.	Proportionate pension.
Denmark	A lump sum equal to six times the annual wage, but not less than $500 nor more than $1,335.	A lump sum computed on basis of earning power lost.
Italy	A lump sum equal to six times the annual wage, the minimum being $600.	A lump sum equal to six times the amount by which the annual wage has been reduced, the minimum being $100.
France	An annual pension of 0.67 of yearly wage.	An annual pension equal to 0.50 of earning power lost.
Spain	A lump sum equal to two years' wages.	A lump sum equal to one year's wage or work at the same pay as before the accident.
Holland	An annual pension of 0.70 of yearly wage.	Proportionate pension.
Sweden	An annual pension of $83.33.	Proportionate pension, but none unless earning power is diminished at least 0.10.
Russia	An annual pension of 0.67 yearly wage, with permission to commute this for a lump sum equal to ten times the yearly wage in full discharge.	Proportionate pension.
United States	A lump sum equal to one year's pay (Act of 1908). An annual pension of 0.67 of yearly wage (proposed Act of 1909).	A lump sum equal to one year's pay (Act of 1908). Proportionate pension (proposed Act of 1909).

POSTGRADUATE COURSE FOR COUNTY SOCIETIES

DR. JOHN H. BLACKBURN, DIRECTOR
BOWLING GREEN, KENTUCKY

[The Director will be glad to furnish further information and literature to any county society desiring to take up the course.]

Tenth Month—Fourth Weekly Meeting

MIGRAINE

ETIOLOGY: Heredity, age, sex, gout and rheumatism, eyestrain, gastrointestinal disorders, etc.

SYMPTOMS: Premonitory. Sensory symptoms, visual disturbances, photophobia, tingling, numbness of extremities, motor symptoms, paresis, aphasia, "ophthalmoplegic migraine." Headache, location, duration, degree. Nausea and vomiting. Vasomotor symptoms. Course of disease and prognosis.

TREATMENT.

TICS

DEFINITION: Etiology: Age, heredity, associated neurotic taint, emotions, local irritation.

VARIETIES: Facial tic, blepharospasm, mental torticollis, coprolalia. Frequency, character, location and extension of spasms.

Monthly Meeting

Psychotherapy in the Treatment of the Psychoneuroses.
The Diagnosis and Differentiation of Hysteria.
The Diagnosis and Treatment of Epilepsy.

Medicolegal

Illegal Practice of Medicine by "Masseur Doctor"—Texas Law Explained

The Court of Criminal Appeals of Texas says, in Newman vs. State (124 S. W. R. 956), that the evidence showed that said Newman inserted in a local paper an advertisement which read: "Prof. J. M. Newman, the Masseur Doctor, has located," etc. "He is the doctor that cures consumption, appendicitis, as well as all other diseases. Now is your time to be healed. Come and see him while he is here." Soon thereafter he undertook to treat a number of persons for sundry ailments, including warts, fever, kidney diseases, and stammering. Testifying in his own behalf, he stated that he was a doctor and a great one; that he could cure the diseases that the M.D.'s could cure, and the diseases that they could not cure; that he had treated various patients of various ailments, and received pay for his services in so doing; that he never used or prescribed medicine in treating his patients; that he used only the massage treatment; that he only rubbed patients for their ailments, and at no time pretended to be a physician or surgeon; that he did not practice medicine, but was opposed to the use of any medicine to effect cures. It was shown by the clerk that he had filed no license or authority to practice medicine.

Section 10 of the Texas medical practice act of 1907 provides that the act shall not apply, among others, to masseurs, in their particular sphere of labor, who publicly represent themselves as such. A fair analysis of section 13 classifies the practitioners who shall be subject and amenable to the law. First, it includes any one who shall publicly profess to be a physician, and claim to effect cures by any system or method; and, second, those who shall treat or offer to treat any disease by any system or method, or to effect cures thereof, and charge therefor. Evidently the words "system or method" were intended to be wide enough in their scope to reach any and every school of medicine, whether based on the administration of pills, potions, or pellets, or the modern—as many persons believe, excellent—system of osteopathy or massage. The history of legislation on this subject in Texas shows that heretofore the Legislature, in dealing with the practice of medicine, had attempted to classify the different branches, and provide for boards for the different schools. Evidently the ineffectiveness of these laws was brought to public attention, because it is certain that the Thirtieth (1907) Legislature, with a view of closing every avenue of escape on technical grounds, and for the protection of the public health, as well as individual citizens, against the quack faker and charlatan, undertook to provide that any person shall be regarded as a practitioner of medicine who professes for pay to cure any kind of disorder or injury by any system or by any method.

The first statement in the advertisement put out by the accused characterized him as a masseur doctor. He advertised himself to be the doctor, and to cure consumption, appendicitis, as well as all other diseases, and warned the public, "now is your time to be healed." Pursuant to his invitation, many people did call to see him, to be healed of their troubles. Can it be said that this man was not holding himself out as a physician, as one who treated and cured diseases? Can it be said that he did not, in the sense that the Legislature understood this term and method or system of treatment, know he was not exempt on the mere ground that he did not use drugs and medicines or surgical instruments?

He was charged with unlawfully engaging in the practice of medicine without having first registered and filed for record the certificate required by law. He was undoubtedly guilty under all the proof, and a judgment of conviction is affirmed.

Admissibility in Evidence of Testimony as to Statements by Patients

The Springfield, Mo., Court of Appeals says, in the personal injury case of Brady vs. Springfield Traction Co. (124 S. W. R. 1070), that a physician who was called to visit the plaintiff after her injury, in testifying as to the condition in which he found her, was permitted to repeat some statements made by her to him in response to questions asked her by him during the examination. It was claimed that this was hearsay and self-serving, and should have been excluded. It was held in Missouri in the case of Gartside vs. Insurance Co., 76 Mo. 446, that such statements could not be admitted in evidence, but that case was overruled by the case of Groll vs. Tower, 88 Mo. 249, the latter case was followed in the case of Squires vs. City of Chillicothe, 89 Mo. 226, and it has since that time been the settled law of the state that such testimony is admissible. The rule is that a physician in describing the result of an examination of a patient may give statements of the patient made to him in the course of the examination which relate to the condition of the patient at the time and which give the physician information proper for him to have in determining the condition of the patient, but statements made by the patient which relate to her past condition or to the circumstances surrounding the injury or the manner in which she received it are not admissible.

"Insanity" Arising During Progress of Difficulty No Defense

The Supreme Court of South Carolina says, in the assault case of State vs. Coyle (67 S. E. R. 24), that "insanity" arising during the progress of a difficulty, voluntarily brought on by the defendant and as the result of a blow rightfully inflicted by his adversary, should not constitute excuse for his after conduct in such difficulty. The reason which sustains the settled law in South Carolina—that voluntary intoxication is no excuse for crime—applies with great force in a case of this kind. Furthermore, the court considers that the barbarity of the defendant's conduct, in beating and cutting the other party a number of times with a knife, afforded no evidence of irresponsible insanity.

Current Medical Literature

AMERICAN

Titles marked with an asterisk (*) are abstracted below.

Boston Medical and Surgical Journal

May 19

1 *The Frequency and Dangers of Fibroids of the Uterus. E. B. Young and J. T. Williams, Boston.
2 Tuberculosis of the Elbow. J. W. Sever, Boston.
3 Rupture of the Uterus in Labor at Term. C. M. Green, Boston.
4 The Treatment of Constipation. M. V. Tyrode, Boston.
5 *Cancer in Massachusetts in 1905. W. F. Whitney, Boston.

1. Fibroids of Uterus.—The following conclusions are drawn by Young and Williams from the study of 971 autopsy records obtained from the Boston City Hospital:

1. Fibroids of the uterus occur in from 7 per cent. to 16 per cent. of all adult females, and in from 7 per cent. to 22 per cent. of all over thirty-five years of age.

2. The age at which fibroids giving rise to symptoms which demand their removal are most commonly encountered is shown by American statistics to lie between thirty-five and forty-five, and by German figures between forty and fifty.

3. Fibroids may, in the main, be divided into three groups: (a) Fibroids of considerable size, nearly all of which produce symptoms. (b) Fibroid polyps, and submucous fibroids which project markedly into the uterine cavity. (c) Small and symptomless fibroids.

4. In fibroids of considerable or large size complications and degenerations dangerous to life occur in at least 10.5 per cent. and for this reason alone the routine removal of all such tumors is indicated.

5. In submucous tumors and fibroid polyps necrosis occurs in over 43 per cent. and the excision of all such growths is, therefore, indicated.

6. Small and symptomless fibroids are absolutely innocuous and of such frequent occurrence that they may safely be let alone. Such tumors, however, when met with in the course of operations for other conditions, should be removed when feasible, because there is always the possibility that they may increase in size.

5. Cancer in Massachusetts.—From the statistics quoted by Whitney it would appear that cancer has really increased in Massachusetts. The rate has rather more than doubled from 1850 to 1875, and almost doubled again from 1875 to 1900. This is true whether the rate for persons at all ages, or persons over thirty years of age, are considered. If the separate sexes and the different decennia of life are compared there is rather more irregularity, but in the main these also give the same result. If the same rate of increase should continue in the future, it is easy to calculate that in 1950 there would be 6,000 deaths to every million persons living over thirty years of age, against the 1,600 deaths in 1900. For 1850 the cancer death-rate for all persons over thirty years of age is 375 for each million living, while for the year 1900 it is 1,578, a difference between them of about 1,200. This would give an average rate of increase for each five years of 120.

6. **Scaphoid Scapula.**—An article on this subject by the same author will appear shortly in THE JOURNAL.

10. **Case of Tabes and Muscular Atrophy.**—The patient whose history is given here by Hunt showed Argyll-Robertson pupils, loss of knee-jerks, presence of the Romberg sign, and great ataxia in all the extremities. At the same time, he showed a progressive muscular atrophy beginning in the hands and extending to the neck and scapular muscles—an atrophy which evinces fibrillary twitchings and a diminished electrical response. It is an atrophy which has advanced with considerable rapidity. Another feature of the atrophy is that it involved not the legs, but the arms, and that it has steadily progressed from the interossei of the hands to the scapular muscles and the face.

38. **Survival of Engrafted Tissues.**—The most complete results have been obtained by Guthrie with ovaries in fowls. In auto-intra-abdominal as well as in subcutaneous transplantations, excellent morphologic results have been obtained. In iso-intra-abdominal ovarian grafts between fowls and between guinea-pigs, functional activity, in addition to anatomic structure, has been completely preserved. Evidence of the complete functioning of such transplanted ovaries is afforded by the altered characters in the offspring.

The ovary of a pure bred white hen was removed and in its place an ovary from a pure black hen was engrafted. Subsequently the white hen laid eggs, and on being mated to a pure white cock, such eggs were incubated and from them were hatched white and black chicks. As yet there is no evidence that simple mutilation of the ovary is a factor in these results. In the single case in which degeneration of an ovary engrafted into a fowl has been observed no eggs were laid. Furthermore, all control hens have produced eggs. On the whole, Guthrie says, we may be reasonably certain that ovarian tissue engrafted into fowls, as in these experiments, may develop and preserve its functional powers to a high degree.

Results with testicles are less complete, no offspring having as yet been produced from engrafted testicles. However, morphologically, the results seem as perfect as with the ovaries, engrafted testicular tissue showing a marked growth and normal structure almost four months after the operation. Transplantation of ovaries and testicles with anastomosis of the nutrient blood vessels have not been practiced sufficiently to permit of comparisons or conclusions. Guthrie says that since results are readily obtained in certain animals hitherto employed by the simple method of transplanting there has been no need for the more complicated operation. But there are good reasons for believing that in larger and older animals, as well as under less favorable conditions, successful results will, perhaps, be more certain after transplantation with anastomosis of the blood vessels than after the simpler operation.

39. **Changes in the Venous Blood Flow.**—While the amyl nitrite invariably produced a marked lessening of the arterial blood pressure, the venous pressure retained its normal value in all cases in which the drug was permitted to exert a general effect of ordinary magnitude. When an artificial circulation through the normal leg was established and inhalations of amyl nitrite were given, no changes in the flow of the perfusion fluid could be detected. It appears, therefore, that the vasodilatory effects of this drug are not incited with the help of central nervous structures.

41. **Studies in Edema.**—Fleisher and Loeb found that adrenalin injected intraperitoneally increases the rapidity of absorption of fluid from the peritoneal cavity, independently of whether the solution to be absorbed is hypotonic or hypertonic or is approximately isotonic with the blood serum. The intravenous injection of adrenalin also increases the absorption of fluid, but not so markedly as does the intraperitoneal injection. Adrenalin injected either intraperitoneally or intravenously increases the quantity of sodium chlorid absorbed. The relative absorption of sodium chlorid—the movement from the peritoneal cavity of sodium chlorid, as compared with the movement of water—is slightly increased when 0.85 per cent. of sodium chlorid solution and adrenalin are injected intraperitoneally; but it is diminished when adrenalin is injected intravenously, or when 1.5 per cent. sodium chlorid solution and adrenalin are injected. When distilled water has been injected intraperitoneally, adrenalin decreases the relative amount of sodium chlorid through the kidneys under the influence of adrenalin.

When 0.85 per cent. sodium chlorid solution is injected into the peritoneal cavity, the blood becomes diluted after two hours and a half. When adrenalin is also injected, the dilution of the blood is less marked, in spite of the increased absorption under the influence of adrenalin. When distilled water is injected into the peritoneal cavity, the blood is diluted equally in control and adrenalin experiments. When 1.5 per cent. sodium chlorid solution is injected, the dilution of the blood is very slight, and in adrenalin experiments it is the same as in control experiments or very slightly greater than in control experiments. The injection of adrenalin causes a temporary increase in the osmotic pressure of the blood, which gradually returns to normal.

In experiments in which 0.85 per cent. sodium chlorid solution was injected intraperitoneally, either with or without adrenalin, there existed a tendency of the peritoneal fluid to attain a greater osmotic pressure than the blood serum. The authors noted a similar condition in cases of general edema in man, in which the osmotic pressure of the ascitic fluid is greater than that of the other edematous fluids or even than that of the blood serum. There exists, therefore, a mechanism that causes the passage of osmotically active substances from the blood or from the tissues into the peritoneal cavity, and that causes the osmotic pressure of the peritoneal fluid to become higher than that of the blood.

The addition of 1.22 per cent. calcium chlorid solution to 0.85 per cent. sodium chlorid solution, increased directly the transudation into the peritoneal cavity merely by inhibiting the absorption.

It follows that adrenalin does not increase the amount of peritoneal transudate found after the intravenous infusion of large quantities of sodium chlorid solution, to which adrenalin has been added, by delaying the absorption from the peritoneal cavity. The increased amounts of peritoneal fluid must be due to increased transudation into the peritoneal cavity; and the adrenalin, in view of its marked effect on absorption from the peritoneal cavity, must increase the movement of fluid into the peritoneal cavity much more strongly than could be assumed from the figures obtained in the infusion experiments.

42. **Thyroid Carcinoma of Brook Trout.**—Marine and Lenhart conclude that the so-called carcinoma of the thyroid of brook trout is, in its early stages at least, nothing more than severe endemic goiter. The possibility that this physiologic hyperplasia may, in some instances, go over into carcinoma is not denied and is in harmony with the more modern views of cancer development. Prevention and cure is favored by adjusting the amount of food and the number of fish to the water supply or by the addition of iodin-containing substances to the water passing through the ponds.

44. **Comparison of Transplanted Tumor and Normal Tissue.**—Rous' paper deals with a comparison of the conditions which determine the fate of transplanted tumor and of a transplanted normal tissue capable of growth. Mouse embryo and mouse-tumor were employed as material. It was shown that individuals differ as hosts for transplanted embryo, some being naturally resistant to its growth, and some favorable, just as is known to be the case where tumor is concerned. The fate of implanted tumor depends directly on whether it elicits from the host a vascularizing stroma. So, too, it is with implanted embryo. Furthermore, mouse embryo, like mouse-tumor, when introduced into rats calls forth a stroma and grows for a brief period.

In attempting to answer the question as to whether individuals favorable (or resistant) to implanted tumor are likewise favorable (or resistant) to implanted embryo, it was shown that the factors of age, nutritive condition, and race, which are potent in determining an animal's status as a tumor-host, act similarly in determining that for embryo. Using embryonic tissue and a method which has proven effective for the production of immunity to implanted tumor, an immunity to implanted embryo was brought about. This immunity manifests itself in the same way as that for the implanted tumor, namely by an absence of the stroma-reaction necessary to life of the engrafted tissue.

Rous believed that these results demonstrate how largely tumor obeys in its adaptation to a new host and growth therein, the general laws regulating a transplanted normal tissue. Besides the phenomena here dealt with, many others that have held the attention of workers with transplantable tumors are probably not peculiar to neoplasms. The present findings emphasize the importance of the tumor-problem as a tissue problem; and they further indicate how essential it is in cancer work to discriminate between characters unique with tumor and those which it possesses in common with normal tissue.

46. **Water Drinking.**—The daily drinking of three liters of water with meals, for a period of five days, by a man 22 years of age, who was in a condition of nitrogen equilibrium through the ingestion of a uniform diet, was productive of the following findings: 1. An increase in body weight, aggregating two pounds in 5 days. 2. An increased excretion of urinary nitrogen, the excess nitrogen being mainly in the form of urea, ammonia, and creatin. 3. A decreased excretion of creatinin and the coincident appearance of creatin in the urine. The decreased creatinin output is believed to indicate that the copious water drinking has stimulated protein catabolism. The appearance of creatin is considered evidence that the water has caused a partial muscular disintegration resulting in the release of creatin, but not profound enough to yield the total nitrogen content of the muscle. The output of creatin is, therefore, out of all proportion to the increase in the excretion of total nitrogen. 4. An increased output of ammonia which is interpreted as indicating an increased output of gastric juice. 5. A decreased excretion of feces and of fecal nitrogen, the decrease in the excretion of fecal nitrogen being of sufficient magnitude to secure a lowered excretion of both the bacterial and the non-bacterial nitrogen. 6. A decrease in the quantity of bacteria excreted daily. 7. An increase in the percentage of total nitrogen appearing as bacterial nitrogen. 8. A lower creatinin coefficient. 9. A more economic utilization of the protein constituents of the diet.

The general conclusion reached by Fowler and Hawk as the result of this experiment is to the effect that the drinking of a large amount of water with meals was attended by many desirable and by no undesirable features.

55. **Angina Pectoris.**—In common with all other observers, Forchheimer finds that angina pectoris is more common in the male than in the female, in the ratio of 63 to 48. The youngest patient in his series of cases was 29 years old, the oldest 76. The longest duration of the recurring syndrome was 17 years, the shortest was found in three who died in the first attack.

Consideration of the various forms of angina pectoris shows the following: In coronary sclerosis there were 56 cases in all; i. e., 29 cases without other appreciable changes in the heart and 27 with other changes. Evidences which Forchheimer considers as pointing to coronary sclerosis are the existence of angina pectoris and certain changes in the aorta or the aortic valves.

In the aorta we find as evidence of sclerosis, some dilatation. Most frequently a soft aortic systolic bruit is detected, which sets in a little after systole, most commonly combined with an accentuation of the second aortic sound, especially characteristic when the blood pressure is low. Over the aortic area are found systolic bruits, differing much in character, sometimes soft, sometimes harsh, but as a rule unlike those of aortic sclerosis due to other causes. Moreover, the second aortic sound is accentuated, which Forchheimer says is a fairly reliable differential sign between arteriosclerotic changes in the valve and in the ordinary form of aortic stenosis.

In one case of syphilitic endarteritis there existed angina pectoris of a very severe type, the physical evidence of a mitral lesion and of myocardiac insufficiency. In 27 cases which were developed on other diseases, the before-mentioned signs were present. The co-existing diseases were chronic myocarditis in 12, mitral lesion in 6, aortic lesions in 4, obesity of the heart in 4, alcohol, diabetes, chronic nephritis, of each, 2; syphilis and cirrhosis of the liver, 1. Nearly all of these had evidence of arteriosclerosis.

In the cases of angina in which coronary sclerosis alone existed we find three dead in the first attack and seven others dead. Of the latter two died of diabetic complications, one of complicating pneumonia in the status anginosus, death being due to acute cardiac dilatation, one of a cerebral and another of a gastric hemorrhage. So that, in all, in only 6 cases could death be attributed to the coronary sclerosis. The duration of the disease in these cases varied from 16 months to 17 years, and all were males. In the 29 cases of coronary sclerosis there is but one female.

When the obstruction is due to thrombosis or embolism, the attack is usually fatal, either immediately or later on, as the result of changes in the myocardium. The attack is always immediately fatal when one coronary artery is closed. As a rule, death occurs instantaneously where the descending or circumflex branches are completely closed, but occasionally the patient survives for a few days as is shown by myocardial infarcts found post-mortem. Forchheimer's experience leads him to believe that when both cardiac asthma and angina pectoris are present from the onset, the outlook for improvement is very small. But he does not agree with Neubürger who states that in coronary sclerosis there are three stages of myocardial changes, which develop and which are always fatal.

So far as the duration of the disease is concerned, aside from those who died in the first attack, in eight the disease lasted from 1 to 2 years; in four from 2 to 4 years, and in 1 for 17 years. Of those alive, four have had the disease from 8 to 10 years, the same number from 5 to 8 years, and 10 from 4 to 5 years.

65. **Plumbism.**—The three indications in the curative treatment of plumbism are, Fantus says, 1, to stop the introduction of the poison into the system; 2, to favor its elimination; and, 3, to antagonize the disturbances produced by it. To stop the introduction of the poison, usually means prompt change of work, not only temporarily, but permanently. An individual who has once suffered from lead poisoning is extremely susceptible to its recurrence, and recurrence in an aggravated form. In favoring the elimination of lead, our first care should be to obtain free evacuations of the bowels, two or three a day, which are sometimes difficult to obtain owing to the obstinate constipation present. It is a mistake, says Fantus, to use in this condition, purgatives that act largely on peristalsis. The salines, and among them most especially magnesium sulphate, should be used in large and frequent doses. The action of the purgative can best be reinforced by the administration of atropin which antagonizes the intestinal spasm, and the use of large oil enemas which are as useful here as they are in other forms of spastic constipation.

After the bowels have been freely opened, and not until then, potassium iodid should be given in doses of 5 grains (0.3 gm.) three times daily. Its exhibition should be accompanied by the free use of water. Anything that increases metabolic activity favors the elimination of the deposited lead. Sweat baths with or without the use of sulphids are useful. A sulphur bath may be obtained by dissolving six ounces of potassium sulphuret in half a tubful of water. But above all, does daily work in the sweat of the brow, preferably out of doors, answer the indication; and this is the kind of work physicians should advise their patients to take up at least for a while.

75. **Mixed Tumors of the Uterine Body.**—Mixed tumors of the uterine body, contrary to those of the cervix, are of infrequent occurrence. Herb found only 8 authentic reported cases, including the one mentioned by her. The youngest patient was 40 years of age. Menstruation had been irregular for 4 years. All the other women were past the menopause, their ages varying from 50 to 62 years. The clinical symptoms, without exception, were pelvic pain, accompanied by a watery or bloody vaginal discharge, which was fetid in some of the cases. The symptoms were of short duration, being from one to six months. A positive and correct diagnosis from curettage was not made. All the women had borne children. All the tumors sprang from the tubal region, except two, which developed in the posterior uterine wall.

They were all single tumors, except Hunziker's, in which there was a hazel-nut size subperitoneal growth which he considered a metastasis. In Penkert's case the tumor, which was 7.7 cm. long and 6.5 cm. wide, sprang from a pedicle scarcely 1 cm. in diameter. In Herb's case the tumor mass extended entirely through the uterine wall; however, it could readily be differentiated from the surrounding musculature. They usually fill the uterine cavity and present an irregular polypoid surface, with dark necrotic areas. They are of rather soft consistency and a grayish or yellowish white color.

Microscopically besides sarcomatous tissue and the different forms of connective tissue, smooth and striated muscle, small cysts, cartilage, and tissue resembling carcinoma may be present. Metastases to other organs or involvement of regional lymph glands were not observed. One patient died of exhaustion seven days after total extirpation. All of the remainder whose histories were followed after operation died from local recurrence within six months, except Lawen's patient, who lived one year.

80. **Necrosis of Bladder with Exfoliation.**—O'Neil claims that necrosis of the bladder occurs as a result, primarily, of interference with the circulation of the organ, aided by bacterial infection. The interference with circulation may be produced by mechanical pressure outside the bladder, or by bacterial inflammation within the bladder wall. The condition is more common in women than in men. The clinical symptoms are vague. Retention (when associated with cystitis) which cannot be relieved with catheter should excite

suspicion. There is a typical cystoscopic appearance by which the diagnosis can be made if the examination is made at a certain time. The prognosis as to life, on the whole, is good in women. In severe cases permanent injury to the urinary function will result. The prognosis in men is good if the membrane is removed. Operative treatment is always indicated in men, occasionally so in women.

85. **Measuring the Capacity of the Renal Pelvis.**—The apparatus devised by Baker consists of a glass burette graduated into c.c. and of 100 c.c. capacity. It is filled with sterile methylene blue solution. A rubber tube leads from the burette, which is fitted into the ureteral catheter by a glass connection. From the top of the burette a rubber tube leads to an air pressure gauge which is fitted with a cautery inflating bulb. With the ureteral catheter in the renal pelvis the bulb is inflated and the fluid is forced into the kidney pelvis under a uniform pressure. When the renal pain occurs, indicating that the kidney pelvis is distended, the reading of the pressure gauge is taken and the amount of fluid which has passed from the burette into the renal pelvis is seen at a glance.

95. **New Operation for Prolapsus Uteri.**—In Venable's advocated procedure, the uterus is lifted to the lower angle of the abdominal wound, the fundus grasped with the tenaculum forceps and held. The thumb and forefinger of the operator are now passed in front of the broad ligaments on either side, respectively, and approximated behind the uterus. The points of the broad ligament easiest approximated are brought together, or if sufficient relaxation does not present for them to meet, a corresponding point on either side is brought to a point on the postero-lateral aspect of the body of the uterus, exerting sufficient tension to see that if so held the uterine position will be as desired and these are selected as the sites for the introduction of a suture. A half-curved, round needle with chromic gut is then passed from before back through the broad ligament just below the ovarian vessels and carried behind the uterus, entering the wall on the postero-lateral aspect as the fundus rounds off to the body and emerges at a similar point on the opposite side; the broad ligament of the left side is now grasped in the same manner, and the needle passed from behind forward below the ovarian vessels, through the left broad ligament. The operator, still holding the left broad ligament, now passes the needle from before backward through the lowest point that it has been ascertained will meet or correspond with a similar point on the opposite side. The needle is then entered into the lateral posterior aspect of the uterus on a line parallel with the suture line above, and emerged at a similar point of exit for the left broad ligament. The suture is then tightened, and if laid correctly the uterus will be swung forward; the tension on the round ligaments producing an anteversion—the sacro-uterine ligaments are made taut and the posterior fornix elevated. If this is the case the hold is relaxed and the posterior surface of the uterus between the points of exit and entrance of the ligature is denuded, as are the portions of broad ligaments that are to come in contact with these denuded surfaces. The suture is again tightened and tied as a mattress suture; the approximated edges of the broad ligament are sutured with continuous catgut in a French needle. The relaxation of the round ligaments may be so great that while this procedure supports the uterus, these are not sufficiently tightened by it, when it will be advisable to add Baldy's procedure or a modification thereof, by fastening the round ligaments behind the fundus with sufficient tension to maintain an antiversion as well as support.

113. **Therapeutics and Medical Science.**—The future hope of the therapeutic art as applying to drugs, Dennis believes lies along the following lines: Dropping out of the pharmacopeia hundreds of medicines which are of doubtful utility or which are with difficulty prepared with accuracy or which duplicate each other in their range of action. The state should provide a laboratory in which would be made examination and tests of medicines to determine their strength and purity, and a law should be made prescribing a fine and punishment for offering for sale medicinal substances varying materially from a standard as defined in the U. S. P. In addition, skilled men should be employed to determine physiologically, when possible, the positive effects of drugs most commonly used. More careful observation should be made and recorded by medical men of the effects of medicines clinically; single remedies should be used more frequently; the ready-made prescription should be largely, if not entirely, dispensed with, as it cultivates habits of carelessness and indolence.

120 Tuberculosis in the Philippines. E. R. Whitmore, Manila.

116. **Specific Treatment of Carcinoma.**—The protoplasmic substances of malignant epithelial tumors in human beings can be injected subcutaneously in large quantities without injurious results. In three cases affected with carcinoma, such

injections given by Coca and Gilman have been followed by the softening and disappearance of tumor masses measuring in diameter from 2 to 4 centimeters. In a fourth case, a rapidly growing lump appeared near the site of the excised cancer two days after treatment. Several days later, when the lump had reached a diameter of 4 centimeters the growth ceased and subsequent microscopic examination showed it to be a firmly encapsulated mass of dying epithelial-like cells. Three other surgically absolutely inoperable cases, in two of which visible amounts of cancer tissue were left unexcised, have remained until now, i. e., for from five weeks to six months, free from recurrence of the disease.

Seven other cases have remained free from a return of the disease for from one to seven months. Two of these were designated as "curable by operation;" three were designated as "probably curable by operation;" and two were designated as "of doubtful curability by operation." In only one case has the disease returned after treatment. In this case the material used for vaccination was rendered inert by too vigorous disinfection. Hitherto no case of sarcoma has come to treatment; however, in view of the failure of the procedure to affect the course of Hodgkin's disease, the outlook for sarcoma is not promising. Tumor cachexia is not increased by the rapid absorption of large quantities of tumor tissue; on the contrary, large injections of tumor material seem to cause the disappearance of the cachexia.

Further experiments seemed to indicate: (1) that the efficacy of the treatment is indirectly proportional to the amount of malignant tissue left in the body, and, within certain limits, directly proportional to the amount of tumor-cell substances injected and to the number of such injections made; (2) that a carcinoma in one individual can be successfully treated with injections of material from a carcinoma of the same kind taken from another individual; (3) that one-half per cent. of carbolic acid does not destroy the "vaccine" within 36 hours if the latter is kept at a temperature of 7 C.

117. **Cultivation of Leprosy Bacillus.**—Attempts have been made by Clegg to cultivate the leprosy bacillus from the spleens of lepers and from cutaneous nodules in cases of leprosy in 10 instances. In 8 out of the 10 instances an acid-fast bacillus was observed to multiply in successive transplants of the cultures of amebas to which the leprosy material had been added. Control plates of the ameba culture without the addition of leprosy material showed no acid-fast organisms present. By heating such an ameba-cholera-leprosy culture a half hour at 60° C. and incubating, isolated colonies of the leprosy bacillus were obtained which grew readily in pure culture when transplanted to the ordinary laboratory media (nutrient agar, bouillon, coagulated egg medium, etc.).

Guinea-pigs inoculated subcutaneously with the pure culture developed in some instances lesions at the site of inoculation which bear a certain resemblance to the leprous lesions of man, both macroscopically and when sectioned and examined under the microscope. The acid-fast organisms were found at the site of inoculation and in some instances also in the spleen. In one instance the acid-fast organism was cultivated from a lesion in a guinea-pig. These guinea-pigs as well as others which received intraperitoneal injections, invariably died during the third or fourth week after inoculation. Inoculations into monkeys have yielded as yet only negative results. The majority of the lepers from whom the material for these cultures was obtained, had tuberculous lesions in their lungs, but the tissues used for the cultures showed no evidence of tuberculosis. The animal inoculations proved that the acid-fast organism cultivated was not the tubercle bacillus.

133 *Experimental Hypophysectomy. S. J. Crowe, H. Cushing and J. Homans, Baltimore.

133. **Experimental Hypophysectomy.**—The authors found in agreement with Paulesco, that a state of apituitarism due to the total removal of the hypophysis leads inevitably to the death of the animal, with a peculiar and characteristic train of symptoms (*cachexia hypophyseopriva*). That these symptoms are not due to surgical trauma or postoperative complications is evidenced by the facts (1) that the same operative manipulations leaving the hypophysis in place and omitting the single step of removal leads to no symptoms whatsoever, and (2) that incomplete removal produces no immediate disturbances. However, even in the case of adult animals death need not occur after a total removal as promptly as Paulesco claimed; puppies may remain in an apparently normal condition for at least three weeks before the terminal phenomena appear. These same symptoms after the same intervals of time, follow the removal of the entire *pars anterior* alone, even though the posterior lobe remains in place. On the other hand, removal of the posterior lobe (necessarily leaving a small amount of *pars intermedia*) not only leads to none of the manifestations of *cachexia hypophyseopriva*, but does not appear to affect the physiologic balance of the animal in any symptomatic way, unless the convulsions and excessive sexual activity which have been seen in a few cases can possibly be ascribed to its absence.

Separation of the hypophyseal stalk, owing to circulatory disturbances, is comparable either to a partial hypophysectomy or to a total removal with immediate reimplantation of the excised tissue elsewhere in the body. The gland becomes reattached and the pathways for posterior lobe secretion (supposed to traverse the *pars nervosa* on its way to the infundibular cavity) may become obstructed by the scar, leading to an accumulation of "hyalin" within the channels of the *pars nervosa*.

Definite constitutional disturbances which may be regarded as manifestations of hypopituitarism have been observed after partial (anterior lobe) removals in a number of animals kept under observation for long periods of time. The most striking feature is a state of adiposity accompanied by (or resultant to?) a secondary hypoplasia of the organs of generation in adults or by a persistence of sexual infantilism in case the primary hypophyseal deficiency antedates adolescence. Polyuria, glycosuria, alterations in the skin and its appendages (such as edemas and hypotrichosis), the tendency to a subnormal body temperature, and psychic disturbances are more or less frequent accompaniments—all of them symptoms which occasionallly occur with states of adiposity and of sexual infantilism in man, in company with certain pituitary body tumors—states, therefore, which presumably are due to hypophyseal (anterior lobe) deficiency.

Animals, in states of hypopituitarism, appear to have a lowered resistance to infection, exposure or disease, conditions which are apt to precipitate the onset of *cachexia hypophyseopriva*. It has been possible, by glandular transplantations, or by injections of anterior lobe emulsion, definitely to prolong the life of animals after total hypophysectomy, and likewise to tide over periods of threatened *cachexia hypophyseopriva* in animals retaining anterior lobe fragments which temporarily may be physiologically insufficient. Boiled anterior lobe emulsions appear to elicit a characteristic (anaphylactic?) febrile response when injected subcutaneously in states of experimental hypopituitarism.

2. **Treatment of Itching.**—According to Bunch, internal treatment should begin by giving preparations of salicylic acid, salol, sodium salicylate, carbolic acid in pill form, arsenic and atropin, or pilocarpin (10 to 20 drops of a 1 per cent. solution). Greater success is usually obtained with sedatives, especially bromid of sodium in combination with cannabis indica, or tincture of aconite with tincture of gelsemium. In more severe cases where insomnia is a marked symptom, hypnotics are necessary. External treatment must, however, always be employed in addition to internal remedies, and one of the simplest and most effective applications is an evaporating lotion. Equal quantities of eau de Cologne and water supplied on lint, or lavender water dabbed on every few minutes, often afford great relief, especially if preceded by hot applications. Sponging with hot water, as hot as can be borne, with or without the addition of bicarbonate of soda, or a hot bath, a vapor or Turkish bath, causes dilatation of the capillaries of the skin, and a subsequent constriction of these vessels induces a more lasting cessation of itching. The addition to a hot bath of oatmeal is usually beneficial. Of cooling lotions the simplest is one containing 2 drams of liquor plumbi subacetatis to 1 ounce of lavender water and 7 ounces of distilled water. One containing hydrocyanic acid, which is very successful, is the following:

	gm. or c.c.		
Dilute hydrocyanic acid	1|5		ʒss
Spirit of rosemary	30	or	℥i
Glycerin	16		℥ss
Water to	300		℥x

Carbolic acid made up in a strength of ʒi to ℥x of water with the addition of ℥ss glycerin and ℥ss eau de Cologne gives a useful lotion, and, if necessary, to any of these lotions, ʒii of cocain may be added to give greater anti-pruritic effect. Alkaline lotions, consisting of either ʒii bicarbonate of soda, ʒii carbonate of potash, or ʒi borax to ℥viii water are all useful for cases where large areas of skin are involved. The addition of a little menthol will increase the effect. Ichthyol, ʒss, sodium bicarbonate ʒiss, spirit of lavender ℥ss, water to ℥viii, is a lotion which often gives relief and may be used for weeks without harmful effects.

In pruritus genitalium, and especially pruritus vulvæ, hygienic and dietetic rules must be adhered to. In more usual cases of pruritus vulvæ, where there is a uterine or vaginal discharge, strict cleanliness must be enjoined, with plentiful use of soap and water and douches of 1 in 5,000 potassium permanganate or 1 in 5,000 perchlorid of mercury, or 1 in 1,000 zinc sulphate. After this a vaginal tampon must be inserted and the external parts covered with Lassar's paste containing 1 per cent. silver nitrate. An ichthyol ointment or paste may be substituted or an ointment containing 30 minims of chloroform to 2 ounces of lard, or the ordinary aconitine ointment. An ointment which often gives good results is chloral hydrate, menthol and camphor āā gr. 45, lanolin and vaselin āā ℥ss.

The more inveterate cases respond well to applications of a Paquelin cautery, to excision of kraurotic skin areas, or to turning up a flap of skin all around the vulva, and division of the afferent nerve fibers. Pruritus of the anus is usually accompanied by some secondary eczema, with the formation of rhagades and thickening of the skin. Ointments are best used at night, bathed off in the morning with olive oil, and the following powder applied: chloral hydrate, camphor āā gr. 40. starch ℥i. A 20 per cent. solution of ichthyol painted on frequently gives relief. Equal quantities of lime-water and black-wash make an excellent application. In the most obstinate cases a rapid application of the actual cautery to the most irritating areas often causes great amelioration of the symptoms. Application of the high frequency current with a glass electrode is occasionally successful, and cases frequently react well to two or three ½ pastille doses of *x*-rays at intervals of a week. A more permanent cure, and one to be recommended in those intense cases when life has become a misery, is that of surgical operation.

4. **Effects of Antisyphilitic Treatment.**—Gibbs and Bayley endeavored to find out by means of the Wassermann reaction the comparative value of various antisyphilitic drugs and methods of administration in 231 cases. Of 138 cases treated with mercurial pills, 66 had received under six months' treatment, and of these 62 gave a positive reaction (94 per cent.). After this period, however, the effect of mercury is clearly shown. Of 33 cases that had received from six months to a year's treatment, 19 were positive (57 per cent.) and 14 negative. Of 25 cases that had received 18 months' treatment, 10 were positive (40 per cent.) and 15 negative. Of 16 cases of inunction treatment all were positive. Of 15 cases treated with mercurial suppositories all were positive. Of 32 cases that had received under six months' pill treatment, 30 were positive with both doses of complement (1/10 and 1/5) (94 per cent.) and 2 were positive with the smaller dose, but showed some hemolysis with the large dose (6 per cent.). Of 11 cases that had received treatment for from six months to one year, 3 were positive with both amounts of complement, 6 were positive with the smaller amount, 2 showed hemolysis with both amounts of complement—i. e., 70 per cent. showed the effect of mercurial treatment.

Of 7 cases that had received 18 months' treatment, 1 was positive with both amounts of complement, 4 were positive with the smaller, but showed some hemolysis with the larger amount. and two showed hemolysis with both amounts of complement—i. e., 86 per cent. showed the effect of treatment. In other words, of the 17 cases which had received over 6 months' treatment only 3 showed hemolysis with the smaller amount of complement, whereas 14 showed hemolysis with the larger amount of complement—i. e., 83 per cent. showed influence of treatment. All those showing a positive result with the smaller amount of complement are active syphilitics.

Of 11 cases of treatment by mercurial inunction, all under three months' treatment, 2 were positive with both amounts of complement, and 9 were positive with the smaller amount, but showed some hemolysis with the larger amount; i. e., 82 per cent. showed effect of treatment, therefore, and this after only three months. Of 17 cases that had received 12 injections of calomel 11 were positive with both amounts of complement, and 6 were positive with the smaller, but showed some hemolysis with the larger amount; 35 per cent. therefore showed effect of treatment. Of 14 cases treated with suppositories for under 6 months, only 3 (21 per cent.) showed any effect of treatment.

11. Surgical Treatment of Gastroptosis.—Of 11 cases of gastropexy recently operated on by Eve, 2 patients were relieved of their symptoms while in the hospital. One patient was quite well 12 months after the operation, but must be excluded because calculi were removed from the common bile duct at the same time that gastropexy was performed, and Eve believes that the symptoms were probably largely due to cholelithiasis. Another patient became melancholic shortly after the operation, was sent to an asylum, and has since been lost sight of. Of the remaining 7 cases, 6 were completely cured; 3 of them reported themselves between 1 and 4 years after operation, and 3 between 3 and 9 months after operation. The remaining patient, operated on 13 years ago, was a neurasthenic, 32 years of age. She was quite well for some time after the operation, but returned to the hospital at the end of a year owing to occasional vomiting and return of pain; but her symptoms entirely subsided while she was in the hospital, and she was able to take ordinary food. Before the operation, the iodopin reaction was obtained in three hours, and 12 months after the operation in one hour and a half, indicating that the motility of the stomach had improved.

Seven patients were treated by gastrojejunostomy. In 3 of them there was dilatation of the stomach in addition to gastroptosis, and 2 of these had also hematemesis. In three other cases hematemesis was a conspicuous symptom. Three of the patients were definitely neurasthenics, but gastrojejunostomy was performed, because in one case there was distinct dilatation and in the two other, incessant vomiting with hematemesis. Of the 7 patients 4 were cured; of these 2 reported themselves 20 months and 7 years, respectively, after the operation, and 2 patients, 8 and 3 months, respectively. The three remaining patients were slightly improved. None of the patients with hematemesis had any recurrence. In fact, Eve has not yet seen recurrence of hematemesis after gastrojejunostomy. The stoma of the gastrojejunostomy probably acts as a safety valve and prevents the distention of the stomach by flatulence, which is one of the chief causes of the hemorrhage.

The two patients treated by Duret's method were improved at first, but ultimately relapsed more or less completely. In one of them gastropexy was subsequently performed with excellent results. Eve concludes that an operation on Beyea's plan, slightly modified, is indicated in the majority of cases of gastropexy which are not amenable to medical treatment. Gastrojejunostomy should be avoided, but may be necessary in certain cases of gastroptosis with dilatation and atony, and when hematemesis is present.

30. Abdominal Surgery.—The cases reported by Curtis are the following: 1. Penetrating wound of a hernial protrusion (self-inflicted); intestine and mesenteric vessels transfixed; intestine and mesentery sutured; death from hemorrhage, external and internal, and shock. 2. A large umbilical protrusion simulating a reducible hernia, found to be a trabeculated sac only, containing free ascitic fluid (cirrhosis of the liver); radical cure; recovery. 3. Tubercle of the extraperitoneal tissue of the anterior abdominal wall, associated with pleurisy and adhesive peritonitis (polyorrhomenitis, or polyserositis). 4. Volvulus of the small intestine, secondary to a hernia into the duodenal-jejunal fossa; one week's intestinal obstruction; reduction; cardiac failure; death. 5. Volvulus of the cecum and strangulation of the descending colon by a traction diverticulum, secondary to chronic peritonitis, causing chronic intestinal obstruction.

45 *Persistent Chronic Bronchitis in Children. J. Allan.

37. Acute Pyelonephritis Due to Bacillus Coli.—It is important, says Rolleston, to be on the lookout for infection of the urinary tract with *Bacillus coli*, because it may give rise to grave constitutional symptoms without any prominent local manifestations; this is particularly so in children, but it may also occur in adults. The *Bacillus coli* may gain a footing in the urinary tract in three ways: 1. Ascending infection, or the upward extension of the micro-organism from the urethra to the bladder, ureters, and pelvis of the kidney. This method of infection occurs in females, especially in early life, and has been explained by the shortness of the female urethra, and by its liability to be infected from the adjacent anus by fecal discharges, and by thread worms. 2. Descending infection, or infection due to the excretion of organisms from the blood into the tubules of the kidney. 3. Transparietal infection, or the passage of micro-organisms from the colon to the kidney, probably by means of the lymphatics. Vaccines made from *Bacillus coli* isolated from the patient's urine have been largely given, but opinion is not unanimous in their favor. Surgical treatment Rolleston regards as unnecessary, except (1) in the most severe cases in which there is suppuration spreading into the kidney substance; (2) in chronic cases in which a pyonephrosis has developed; (3) in secondary cases in which there is a calculus in the kidney.

45. Chronic Bronchitis in Children.—In the treatment of persistent chronic bronchitis the first point is that the causative factor must be determined and if possible remedied. Remove enlarged tonsils and adenoids. Mouth breathing in any case is a direct menace to the child's health, and in the tuberculous will tend to aggravate the constitutional condition. Nasal obstruction from whatever cause should be at once treated. As soon as possible after the operation the child should begin to carry out respiratory exercises, to reestablish breathing through the nose. The child's dietetic régime should be carefully investigated, and in necessary cases a suitable dietary should be drawn up. The fault may lie in habitual overfeeding or in wrong feeding. All cases will be benefited by a modified diet, and in cases secondary to chronic indigestion it should be strictly enforced. In general terms the reduction of the carbohydrate intake and the interdiction of sweet things are the important factors in modifying the diet.

Allan prescribes a diet similar to that advised by Dr. Robert Hutchinson in chronic dyspepsia in children. The following should be avoided: Starchy puddings, such as rice, sago, tapioca, arrowroot, and cornflour sweets, sweet cakes, sweet fruits, jam, honey, marmalade, potatoes, turnips, carrots, etc.

The diet should consist chiefly of stale bread, dry toast with butter or drippings, eggs in any form, beef, mutton, fish, chicken, bacon, tongue, green vegetables in moderation, custard, plain puddings, stewed prunes, figs, etc. The child should be trained to eat only at meal times and should not be given anything between meals. Tea, coffee and stimulants should be prohibited. In the absence of definite gastric symptoms, Allan relaxes the restrictions somewhat, allowing more carbohydrate food, and a little weak tea, but forbidding sweet things as far as possible. General hygienic measures are of primary importance. These children should be in the open air as much as possible. The rooms which they inhabit should have good ventilation, and the window in the sleeping apartment should be kept open night and day. The clothing should be of such material as to afford sufficient warmth without being too heavy. Outdoor sports, in the absence of any cardiac disability, are to be recommended. Cold sponging is invaluable. A change of residence is often beneficial. With regard to medicinal treatment, general tonics should be prescribed. The cough under certain circumstances may call for treatment, but it is often found that under this general tonic treatment, improvement as regards this symptom takes place.

61 *Compulsory Isolation in Leprosy, Smallpox, etc. (A propos d'un cas de lèpre contagieuse. Réflexions sur l'isolement obligatoire de certains malades infectieux.) J. Courmont, M. Lannois and Dufourt.

61. **Contagious Leprosy.**—Courmont has a patient with leprosy whose nasal secretions swarm with lepra bacilli. The man ascribes the infection to cleaning a building in Colombia, South America, which had been used at one time for lepers but was then empty. A few months later symptoms of leprosy developed. He has been serving as a porter during the last two years in France, and Courmont discusses the problem of social hygiene presented by such a case, as there is no legal means of preventing his spreading the infection broadcast. The nose was the principal seat of the ulcerations. The throat also was involved. As the man is only 39, lives a wandering life and emits every day several grams of secretions swarming with bacilli, and is liable to acute exacerbations at certain intervals, he is certainly a peril to the public. Courmont believes the passage of some wandering leper of this kind may have been the origin of certain foci of leprosy in France. He urges modification of the law to enforce compulsory isolation of contagious individuals until their bacteriologic recovery. In the Scandinavian countries, he says, both rich and poor seek the hospitals, and this is the true solution of the question. He states that it is, from the social point of view, more important to isolate the contagious than the insane. Prophylaxis of scarlet fever, diphtheria, leprosy and smallpox requires compulsory isolation from the beginning of the disease to the end of the contagious period.

70 *Toxicity of Echinococcus Cysts. Direct Toxicity and Anaphylaxis. L. Boidin and G. Laroche.

68. **Leucodiagnosis of Cancer.**—Achard, Bénard and Gagneux have demonstrated that the presence of certain cellular elements in the organism confers on the leucocytes the faculty of reacting to the products of these cells. This reaction is influenced by the normal or pathologic modifications occurring in the functioning of these cells. Their tests *in vitro* seem to show that this leucocyte reaction is specific to the pathogenic or normal substance circulating in the organism, thus revealing the physiologic or pathologic state connected with the intoxication, infection or functional disturbances in the organ in question. They have applied this method to various infections and diseases and in this article report the findings in 49 cases of cancer, all positive, and in 24 non-malignant cases, in which the reaction was always negative. The test is made with extract of macerated cancer tissue. Mixed with this extract the leucocytes from healthy persons seem to lose their phagocytic property, while leucocytes from persons with cancer are not affected by the extract. The phagocytic properties are tested with one drop of a yeast emulsion in test tubes containing the extract and a drop of blood from the patient.

70. **Toxicity of Echinococcus Disease.**—Boidin and Laroche call attention to the fact that the fluid from an echinococcus cyst is scarcely at all toxic for animals, and yet the absorption of a few drops during a clinical operation is liable to cause sudden and severe symptoms indicating serious intoxication. Chauffard explains this as the result of anaphylaxis, and experimental research is here reported which justifies this view. There is evidently a slow, chronic, toxic action going on all the time, as is revealed by biologic tests, fixation of complement and eosinophilia. Under the influence of this chronic intoxication the patient becomes sensitized, as it were, and the introduction of a new dose of the toxin, even a small one, is liable to induce shock due to anaphylaxis.

82 *Operative Treatment of Placenta Prævia. M. Henkel.

82. **Operative Treatment of Placenta Prævia.**—Henkel compares the experiences at various clinics with different technics. His conclusion is to the effect that abdominal Cesarean section is indicated for placenta prævia centralis whether the fetus at term is living or not. Earlier in the pregnancy the vaginal route is preferable, clamping the uterine vessels on both sides. With placenta prævia lateralis or marginalis either the inflatable bag or version can be applied. In a recent series of 26 cases of placenta prævia in which treatment was applied on these principles, only 2 of the patients died, while 6 patients and half of the children died in a preceding series of 30 cases in which the metreurynter had been exclusively used.

93 *Injuries of the Semilunar Fibrocartilage of the Knee. (Verletzungen der Kniegelenkszwischenknorpel und ihrer Verbindungen.) F. Kroiss.

89. **Fatality After Momburg Belt Constriction.**—The patient in the case reported was an aged and infirm man who had been crushed between a wagon and a stone wall, the contusion being in the right inguinal region. Two hours after the accident signs of laceration of the femoral artery compelled operation and the rubber tubing was wound around the waist to prevent further hemorrhage, according to the Momburg technic. As the tubing was unwound afterward the patient collapsed. Autopsy disclosed stasis hemorrhages in the pleura and edema in the lungs and a little bloody fluid in the pericardium. These evidences of severe congestion in the upper part of the body Amberger ascribes to the action of the constricting tubing in this particularly decrepit patient.

93. **Injuries of the Meniscus and Their Treatment.**—Kroiss reports from the Innsbruck clinic in charge of Schloffer 32 cases of this kind and reviews 214 from the literature, giving a summary of each, with the special treatment and the ultimate outcome so far as known. Removal of the meniscus gave good results in 82 per cent. of the cases, while a perfect result was obtained in 92 per cent. of the cases in which the meniscus was merely sutured.

97. **Pulmonary Tuberculosoid.**—Neisser and Bräuning have coined this term to express a common condition in which the patients present subjective signs of pulmonary tuberculosis and some susceptibility to tuberculin, unstable temperature but no fever, and tenderness in the region of the bronchial glands, but all these signs gradually subside and the patients remain constantly well. In the 1,900 persons who have passed through the tuberculosis observation station at Breslau in the last ten years, 300 presented this tuberculosoid condition, and examination from 4 to 10 years later has shown that the condition is the result of tuberculous infection in a person who is not predisposed to the disease and is thus able to resist general infection. The process remains small and circumscribed, and either heals or passes into a latent phase. If he dies from some intercurrent disease, the findings are those which Naegeli has described. This prelatent stage of pulmonary tuberculosis may itself become chronic, the patients being then classed as anemic or pseudoanemic by their ailing but never really sick state, but their susceptibility to tuberculin and the tenderness of the bronchial glands reveal that they are chronic tuberculosoids. The primary focus is not able to induce actual pulmonary tuberculosis but still keeps its foothold. The importance of this conception is that in these cases the patients did not take any treatment or merely a very insignificant one. If they had been given a course of treatment the recovery or passage into the latent phase would have been ascribed to the treatment. In the spontaneously recovering cases the observer might have been tempted to doubt his diagnosis of tuberculosis. Among 90 tuberculosoids reexamined after several years, 57 were cured or in a latent phase, and in 28 the condition had become chronic although better than at the first examination. Only 2 out of the total 300 tuberculosoids have died, and both succumbed to an intercurrent affection. In conclusion Neisser and Bräuning call attention to the peculiar liability of certain occupations to develop this tuberculosoid condition; it was encountered in 38 per cent. of 269 cabinet makers and locksmiths; in 32 per cent. of 68 painters and printers; in 70 per cent. of 47 girls employed in stores, but only in 3.7 per cent. of 325 housemaids and in 2 per cent. of 179 sailors, gardeners or roofers, or men otherwise employed out of doors.

98. **Loading Test of the Stomach.**—Bloch has the patient take a suspension of bismuth and he is then radiographed. He then eats an appetizing meal of beefsteak and potatoes, eating as much and as fast as he can, and is then radiographed anew at intervals. The normal stomach under these conditions

enlarges evenly, spreading wider, but the pathologic stomach is dragged down by the weight of the ingesta and the latter accumulate at the bottom, which is the only part that spreads out wide.

106 *Leukemic and Pseudoleukemic Disease of the Upper Air Passages. (Die leukämische und pseudoleukämische Erkrankung der oberen Luftwege.) R. Imhofer. Commenced in No. 3.
107 *Traumatic Pneumonia. L. Müller. Commenced in No. 3.

106. **Disturbances in the Upper Air Passages with Leukemia and Pseudoleukemia.**—Imhofer discusses the manifestations in the throat and nose of a tendency to leukemia and pseudoleukemia. With leukemia the mouth and throat may present a diffuse catarrhal affection, or the lymphatic tissue, follicles and tonsils may alone be involved, or the lesions may be of an ulcerative or gangrenous nature. In differentiation great stress should be laid on a striking and rapidly increasing enlargement of the tonsils—they may become four or five times the normal size; small suggillations are also characteristic. When such are discovered the blood should always be examined under the microscope. Hanszel has reported a case of acute leukemia in which a deep ulcer developed in the tonsil, involving the uvula, and staphylococci were cultivated from the lesion. The connection with an angina is particularly evident in a case reported by Hanszel in which a young man had a severe sore throat, followed by fatigue and emaciation after a fall from a horse. Four weeks later the angina recurred with ulceration in the tonsil, enlargement of the glands throughout and death in four weeks from acute leukemia. Kubler found a yellowish deposit on gums and tonsils in a previously healthy soldier, and their leukemic nature is evident, as a tendency to hemorrhages at various points and multiple glandular tumors were also observed. In 4 cases on record operations for removal of adenoid vegetations or enlarged tonsils in leukemic children proved fatal. In one case the child died suddenly several hours after an extensive postoperative hemorrhage. In the other cases 2, 3 or 4 weeks elapsed after the operation before the child succumbed to increasing weakness and aggravation of the signs of leukemia, suggesting that the operation had transformed a chronic leukemic process into an acute form. The danger of hemorrhage is thus not the main peril in operations on the upper air passages in leukemia; the possibility of rousing a mild chronic process to severe acute manifestations must be considered. In one of the above cases this transformation did not occur until after a second operation for recurrence of the leukemic enlarged tonsils and adenoid growths. Consultation with the little patient's family physician is extremely important, if practicable, before attempting any operation on adenoids or enlarged tonsils. On the slightest suspicion of leukemia the most careful examination should be made, and only when leukemia can be certainly excluded should the operation be performed except for vital indications. Especially suspicious is the simultaneous enlargement of all the tonsils and of the regional glands, although such may be encountered with tuberculosis. Rapid recurrence after operation is also suspicious of leukemia; also when the swollen parts are redder than with tuberculous lesions and the tumor seems harder; edema is not observed as in tuberculous lesions in the throat. The blood findings are the main reliance for differentiation. Lymphosarcoma is distinguished by its progressive encroachments in the vicinity. Treatment of leukemic affections of the nose and throat can be only symptomatic and that for leukemia in general and this has little to show to its credit. Tracheotomy is indicated as a last resort but did not avert the fatality in the cases on record. In one there was necrosis of the fascia and fatal bronchopneumonia; pressure necrosis and gangrenous destruction are liable also after intubation. The same conclusions apply to pseudoleukemia and to lymphosarcoma except that the course of the latter is more prolonged as a rule, and patients with lymphosarcoma stand operations much better than those with leukemia or Hodgkin's disease. Beale, Storck and others have reported long survivals after removal of the lymphosarcoma and Abercrombie performed three operations for recurrence, the patient finally succumbing to a complicating erysipelas. Lymphoid and myeloid chloromas seem to stand midway between leukemia and lymphosarcoma, but they do not involve adjoining tissues and there is no enlargement of the spleen.

107. **Traumatic Pneumonia.**—Müller reviews 127 articles that have been published on the subject of pneumonia following external violence or inhalation of dust or gas or aspiration of a foreign body. He summarizes the various cases reported, emphasizing the special features of each. The list includes 21 articles published since 1900, among them J. J. King's article in The Journal, March 21, 1908, page 939. Litten reported 4.4 per cent. of traumatic cases in 320 cases of pneumonia in his experience during 6 years. The acute pneumonia may develop into a chronic phase, but Müller could find very few records of traumatic pneumonia commencing in an insidious chronic form. Hadlich's experimental research has shown that a chronic florid inflammatory process may persist in the lung unsuspected long after the healing of an experimental stab wound not far away. In the few clinical cases of chronic traumatic pneumonia on record a tuberculous element seems probable in some. Partsch states that the numerous small foci of extravasated blood from a contusion of the lung may induce a syndrome suggesting insidious phthisis but that complete recovery is the rule. Stern is convinced that chronic non-tuberculous inflammation of the lung occurs more frequently than is generally recognized. In a case in which pneumonia developed two days after a boy had been hit on the back by his teacher, the court refused to admit that the blows on the back, the head bent forward, could have been responsible for the rapid development of acute pneumonia. In Weigel's case, also, no forensic connection was admitted between a slight injury of the head in 1893 and a fatal pneumonia complicated with meningitis in 1906. In another forensic case a young man developed fatal pneumonia two days after a jar from another swimmer in a swimming tank. He became unconscious from the impact but was rescued in about four minutes. The verdict of traumatic pneumonia relieved the swimming-master of responsibility; the autopsy findings showed that no water had been aspirated.

112 A Century of Vital Statistics in a Swiss Commune. (Hundert Jahre Geburts- und Totenstatistik der Kirchgemeinde Ermatingen.) O. Nægeli.

108. **Treatment of Contractures in Hemophilics.**—Hübscher describes the technic with which he was able to correct the contractures in the knees of a boy of 15, a typical bleeder, from a family of bleeders. The process in the knees was the typical hemophilic joint process, and there was a fistula in the arm from a hematoma in the biceps, which bled a little at times. Before attempting treatment, Hübscher injected 10 c.c. of normal horse serum into the region of the pectoralis, and within two days the fistula ceased to bleed. The contracture was corrected with a plaster cast from hip to toes, cut out at the knee, with elastic traction on the leg by means of rubber tubing fastened to a projecting iron frame. The device is illustrated. The boy was not kept in bed and by the end of the month he was able to use his legs. The last trace of contracture was then reduced under ether after another injection of horse serum; there was no bleeding at any time. The family physician was instructed to keep up the prophylactic injections of serum every six weeks or two months afterward for a time. The influence of the serum was striking in this case; under its protection measures were successfully undertaken even the attempt at which previously had brought on menacing hemorrhages. He used the serum less than two hours after it had been taken from the horse. By this means he believes that it will be possible to avoid fatalities such as those König has reported in which boys of 13 and 18 succumbed to hemorrhage after an operation on the knee for supposed tuberculosis. A cousin of Hübscher's patient met

with this same fate. Tilmann also lost a patient from this cause after an operation on a hemophilic joint which had been mistaken for a lipoma. Fröhlich mentions the case of a soldier who was operated on for a supposed abscess in the hip joint, the fifth process of the kind, each time the fever and hard edema suggesting an acute osteomyelitic process. The patient bled to death thirty-six hours after the operation. When a process of this kind, generally bilateral and recurring at intervals, develops in a youth of a pale aspect, and especially if Roentgen-ray examination shows the unmistakable contracted bleeder joint, no operation should be attempted if avoidable; but if required, the patient should be kept under the prophylactic influence of injections of normal horse or human serum. In dubious cases, he remarks, it is much safer to make the injections sometimes when they are not needed rather than to omit them in the true bleeder cases.

109. **Traumatic Tabes.**—Ladame's patient was a previously healthy man of 52 who developed symptoms of incomplete tabes a few months after a severe railroad accident followed by a traumatic neurosis, the symptoms of which persisted for years with varying intensity. Although everything in this case seemed to speak for traumatic tabes and there was nothing to suggest syphilis in the family history, yet Ladame is inclined to believe that an ignored syphilis was at the root of the nervous affection, as the patient had had a brief mild gonorrhea in youth. No tests were made for the Wassermann reaction; the Argyll-Robertson sign was pronounced.

110. **Tides and Predisposition to Disease.**—Brunner has been keeping records for thirty years in regard to the incidence of disease in connection with the reduction in the atmospheric pressure which accompanies the periods during which the attraction of the moon is supplemented by that of the sun increasing the effect of gravitation. This tide in atmospheric pressure is manifested by the changes in the weather and possibly also by changes in the circulation of the sap in plants, the vitality of pathogenic germs and the blood pressure in man. The maximal effect is therefore experienced when the moon is nearest the earth, and especially at the time of the great spring tides. He gives a table of the date of onset of the first symptoms of pneumonia in all cases of pneumonia in his charge during the last 2 years, a total of 25 cases. In 6 cases the onset was within 2 or 3 days of each other in different villages, and in 21 it coincided with the new or full moon, only 4 occurring at the first or last quarter of the moon. He thinks that the influence of the maximal effect of the attraction of the moon is evident also in the commencement of labor, the incidence of epileptic seizures, crises in disease and death.

116 Fo[illegible] Calories in Infant Feeding. (Die einfache Grundlage der kalorische [illegible]uglinge.) G. Heimann.

113. **Banti's Disease.**—Momm reports a typical case, the history showing some connection with an accident, the patient having been run over by a bicycle. Apparently complete recovery followed removal of the spleen four years after the first symptoms, and the patient feels entirely well at present, six months after the operation. The case shows that ascites may occur quite early in the disease; it is probably the result of abnormal composition of the blood and obstruction of the lymphatics in consequence of swelling of the mesenteric and retroperitoneal glands.

114. **Non-parasitic Chyluria.**—In Hnatek's case, a previously healthy woman of 33 suddenly noticed milky discoloration of the urine and the passage of villus-like clots, with pains similar to stone colic. The night urine contains 7.73 c.c. albumin to the liter; the day urine is normal unless the patient reclines, when it becomes chylous. Catheterization of the ureters shows that the left kidney eliminates four times as much fat as the right, suggesting new problems, as the amount of urine is about the same from each.

115. **Gastrointestinal Disturbances from Swallowing Pus from Sinusitis.**—Zabel has encountered a number of cases of subjective gastric disturbances for which a sinusitis was responsible. The disagreeable sensations were most marked in the morning. Bad taste in the mouth, gases in the stomach, lack of appetite and loss in weight, and altered stomach content is suggestive of chronic catarrh. His experience warns that in all cases of gastric disturbance it is wise to seek for the presence of pus in the nasal apparatus or throat, in the teeth or from a cavity in the lungs. He found flagellates numerous in the stomach content in 2 cases described in detail; the patients were boys of 9 and 15 and the microscope showed numerous scraps of mucosa in the stomach content swarming with the parasites, and with traces of punctate hemorrhages. The disturbances in the intestines from this cause may be so serious as to suggest appendectomy.

130 [illegible] F. Weber.

117. **Resection of Elbow with Interposition of Muscle Flap.**—Reiner reviews the outcome in 23 cases of injury or disease of the elbow requiring resection and treated by interposition of a flap of muscle tissue. The arm was left fairly movable in 82.6 per cent. of the cases. The results were invariably good in the tuberculous cases, the local process healing, and in all the results far surpassed those attainable with other technics, he is convinced.

121. **Balsam of Peru in Treatment of Wounds.**—Sickmann's experience with balsam of Peru and his experimental studies have confirmed, he says, the great advantages of this method of treating recent accidental wounds. The wound is covered with a compress while the vicinity is scrubbed, shaved or washed with alcohol and benzine and painted with tincture of iodin. Then the compress is removed, the minor bleeding arrested, the superficial wound secretions mopped up and, without any further preparation or sterilization, the balsam is poured into the wound until it overflows, after which a dry sterile dressing is applied. The balsam is so heavy that it sinks down into the remotest crevices. The dressing is not changed for a week unless fever or other signs of infection develop. This is by no means an ideal method of treatment, he remarks, but the results are remarkably good in comparison with the simplicity of the method. Especially for the first dressing of the wound, which generally decides the fate of the lesion and possibly of the patient, this technic renders inestimable service. It is also extremely useful in old torpid processes to stimulate them to more active repair. He often uses the balsam, instead of tamponing, to fill up and thus close the holes left by drains in operations on the joints. No inconveniences were ever observed from the use of the balsam; it seems to have a slow but unmistakable antiseptic action on the germs commonly encountered in recent wounds, while its physical and chemical properties oppose putrefaction. It has, further, a positive chemotactic action which enhances the local resistance.

126. **Removal of Bladder for Carcinoma.**—Petrow reports a case in which the patient was in good condition 9 months after total removal of the bladder for malignant disease. In a second case the disease was far advanced and the heart dilated, and the patient succumbed during the preliminary operation. He reviews 64 cases he has found in the literature, the immediate mortality having been 50 per cent., 11 others succumbing in from 2 to 5 years, while 13 others are still living from a month to 16 years since the operation. The ureters were implanted in the intestine in 11 cases, including 6 in which the patients are still living after from 4 to 18 months, while the survival was from 3 months to over 5 years in the 5 other cases. In the 3 cases in which the ureters were implanted in the vagina, the patients are still living after 3 months, 8 months and 16 years. In 9 cases the ureters were implanted in the skin in the lumbar region front or back, and 5 of the patients died in from 2 to 13 months; the others are still living after 4 months in 1 case and 2 years in the 3 others. The communication issues from Oppel's surgical service at St. Petersburg. Petrow advocates operating on the ureters first, not removing the bladder until two weeks after they have been implanted at the desired point. He recommends the intestine for this. The laparotomy for the purpose allows oversight of conditions before the final operation. The outcome depends on the state of the kidneys, as a rule; if they are diseased, as in his second case, there is not much hope of a successful termination.

129. **Effectual Parathyroid Treatment of Parathyreopriva Tetany.**—The thyroid gland was the seat of a sarcoma in the case reported by Schneider. The cancer involved also the parathyroids, and removal of the growth was followed by severe tetany. Fresh parathyroid substance from the horse, dried and powdered, was given, and he says that a specific favorable effect on the tetany was unmistakable. The patient was a woman of 40; she succumbed before the year was out to the progress of her malignant disease.

135. **Artificial Dilatation of the Uterine Cervix.**—Hannes protests against instrumental dilatation, as it merely stretches the tissues without inducing physiologic dilatation; the latter can be realized with the elastic inflatable bag. This simulates the natural process of stimulation of the cervical musculature to rhythmic contraction by the gentle, gradual pressure of the ovum from above on the cervix. If it is impossible to wait for this natural process, he advises slitting the cervix—vaginal Cesarean section. The incision is under control, which is never the case with the tears resulting from instrumental dilatation

139. **Epilepsy and the Thyroid.**—In the case reported by Siegmund, certain evidences of thyroid insufficiency accompanying the epilepsy suggested possible benefit from thyroid treatment which was systematically applied. The patient was a girl, 9 years old, and the constant improvement has confirmed the assumption that defective thyroid functioning was an important factor in the epilepsy. The child has been under observation for two years.

140. **Obstacles to Normal Circulation and their Importance in Pathogenesis.**—Sperling comments on the interference with the circulation that may be entailed by distention of the stomach or intestines and weakening of the heart action and nerve force from chronic overexertion. In a case described a girl nearly 10 years old had attacks of nervous symptoms, including tonic-clonic spasms, which various courses of treatment by eminent neurologists failed to relieve. Sperling differentiated the trouble as the result of interference with the circulation from overdistention of the gastrointestinal tract. During the intervals between the attacks the skin was pale, the extremities cold, the pulse rapid and the abdomen prominent. The stomach and intestine were distended to two or three times the normal size and this interfered so much with the circulation in the trunk that a reflex nervous syndrome had developed. His assumption as to the nature of the trouble was confirmed by the complete recovery from the nervous troubles as soon as conditions in the gastrointestinal tract had been restored to normal.

150 Treatment of Tuberculo[illegible] (Altes und Neues zur Behandlung der tuberkulösen Hämoptoe.) A. Heisler and E. Tomor.

145. **Fulguration in Treatment of Uterine Cancer.**—Richter reports the experiences with various measures in 45 cases at the gynecologic clinic at Dresden in charge of Leopold. Fulguration was systematically applied in all and the palliative effect was very good in some cases, the pains, bleeding and ichor being promptly arrested although recurring later. As fulguration can be applied without general anesthesia, it has this advantage over cauterization. Another advantage is that the tissues are so modified by the fulguration that a cancer which at first seems entirely inoperable may be found to be within the limits, as what was supposed to be carcinomatous involvement of the surrounding tissues may prove to be merely serous infiltration. The best results were attained when the fulguration was supplemented by acetone treatment; the latter alone is also very useful. This is the application of crude acetone, poured into the vagina through a glass speculum until it fills half the speculum. It is left here for 10 minutes or longer and is then swabbed out and a glycerin tampon introduced into the vagina. This procedure is repeated from two to four times a month; the acetone hardens the tissues so that bleeding and ichorous secretions are checked, and it has a most beneficial palliative action. The benefit was striking in one case of inoperable cancer treated with the acetone alone. The patient has had about 80 of these applications during twenty-one months and looks and feels well except for pain in the pelvis, although the growth is so extensive that it almost fills the vagina and compresses the rectum. Another patient comes regularly twice a month from a long distance, requiring over a four-hour railroad journey, for her acetone treatment. The number of cases of uterine cancer in which fulguration has been used is not over 80 to date, he says. He knows of no other means by which patients can so easily

be relieved for a longer or shorter time. Although the fulguration has no permanent effect, it can be repeated at need. It was applied about four times in each of the cases reported in detail.

146. **Cancer of the Esophagus.**—Tiegel thinks that the prospects for recovery are not bad after radical operations on cancer low down in the esophagus. He advocates opening the abdomen and mobilizing the growth from below as a preliminary to the operation proper. He knows of only 2 cases in which the entire operation was done at one sitting. Exploratory thoracotomy is well borne by these patients. In one case the stomach and esophagus were readily reunited after resection of the sound esophagus for 6 cm. He regards tumors high in the esophagus as still beyond the reach of the surgeon.

147. **Early Diagnosis of Multiple Sclerosis.**—Finkelnburg calls attention to certain sensory disturbances which permit the diagnosis of multiple sclerosis at an earlier stage than is otherwise possible, reporting 3 typical examples and a further group of cases in which the ultimate outcome confirmed the presumptive diagnosis based on the change in deep sensibility in the arms while the superficial is still intact, accompanied by an inability to recognize objects by the sense of touch. These sensory disturbances subside to recur again after a longer or shorter interval; not until long afterward does the clinical picture of multiple sclerosis become unmistakable. In one of the cases reported a man of 26 without trauma or preceding infectious disease noticed the progressive development of sensory disturbances in the right arm, shoulder and side of the chest, as if the arm were "asleep," with occasionally severe pain and incapacity to use the arm in drawing, which was his occupation. After being fully incapacitated for a time, complete use of the hand was gradually regained and retained for 6 years when the symptoms returned, but affecting more the legs and vision, and soon progressed to unmistakable multiple sclerosis. In another case a young man presented a transient paralysis of the left arm, aphasia, dysarthria, and disturbances in the deep sensibility of the right hand. No signs of pressure on the brain were observed at any time but the affection rapidly progressed, with spastic paresis, anarthria, bladder disturbances and death in less than six weeks. The diagnosis wavered between multiple sclerosis and multiple neoplasms, but autopsy six weeks after the onset of the severe phase revealed multiple sclerosis. In 2 other cases the sensory disturbances were restricted to the arms—merely isolated changes in the deep sensibility of the right or left hand, accompanied by paresthesias. These patients were men of 19 and 22. No other nervous disturbances were evident except a tendency to slight paresis in the limb involved and to slight nystagmus or suggestion of ataxia in the arm. In both cases the symptoms gradually subsided completely and the patients still feel well 4 and 2 years afterward, but there are signs in both of oncoming multiple sclerosis. In 8 other cases of fully developed multiple sclerosis he was able to ascertain a history of sensory disturbances like the above before the development of the actual trouble. The interval was as long as 10 years in some of the cases. Especially characteristic is the isolated disturbance in the deep sensibility and the course of development in its successive progression and complete decline.

157. **Tumors in the Pineal Gland.**—Pappenheimer gives the clinical and autopsy details of the case of a boy of 10, previously healthy, who developed symptoms of a brain tumor; the sudden onset and brief duration of the affection were particularly noticeable. The main symptoms had been headache, vomiting, stupor and severe optic neuritis. A tumor the size of a walnut was found in the region of the pineal gland, its characteristics entitling it to be called an ependymal neuroglioma. He compares the data with those of 37 other tumors of the pineal gland he has found on record, Virchow opening the list in 1863. The age of the patients ranged from 2, 4, 6 and 9 up to 50 and 59 years. Only 3 were women in the 31 cases in which the sex was mentioned.

161. **Pathogenesis of Epileptic Seizure.**—Fuchs reports experimental research on convulsions of toxic origin (cocain) and on means to control such convulsions. It seems to be evident that sodium bromid has a specific action on the cortex, he concludes, and that its action is restricted to the cortex. It thus controls the cortical elements of the epileptic tendency, but has no influence on the subcortical element, the tonic spasm. His research has shown further that the effect of the administration of the bromids can be gaged by the difference in the behavior of the reflexes with a cortical lesion in one hemisphere. The reflexes on the side affected become abolished under the influence of the bromid, while they persist unmodified on the sound side. This reaction to the bromids was pronounced in 18 out of 21 cases of epilepsy with hemiplegic symptoms. For example, a boy with right hemiplegia had the superficial abdominal reflexes alike on both sides. Forty-five minutes after ingestion of 1.5 gm. sodium bromid the abdominal reflexes on the affected side were abolished and the Babinski positive while on the sound side there had been no change in the reflexes. This behavior of the reflexes was striking in 6 cases, as he relates in detail. In the remaining 59 cases of epilepsy little if any benefit was derived from the bromids. There was nothing in these cases to indicate a cortical lesion.

163. **Relative Benignity of Certain Cancers.**—Koschier reports in detail 8 cases of sarcoma or carcinoma in the upper air passages in which the cancer spontaneously retrogressed or subsided after an entirely inadequate operation. The growths must have been of very slight virulence and the individuals exceptionally resistant. In one case a woman of 28 had no recurrence for nearly three years after partial removal of an epithelial carcinoma in the nasopharynx. When it recurred, mercurial treatment was instituted which seemed to aggravate the growth and the patient soon succumbed to its progress. In another case a woman of 42 refused to permit the removal of an epithelial carcinoma in the nasopharynx and accustomed herself to breathing through the mouth after slight improvement had followed the exploratory incision. The cancer has persisted through 9 years without inducing cachexia, and the patient is free from further disturbances, except that vision in one eye has been lost in the last year, and there is now exophthalmos. He does not know of another case in which a histologically diagnosed carcinoma has persisted free from glandular or other metastasis and cachexia for more than 9 years. The features of these cases bear some resemblance to those of mouse cancer; they suggest the pos-

sibility that recoveries after extensive operative treatment may sometimes be due to the nature of the process rather than to the surgeon's skill.

169. **Functional Tests of the Heart.**—Tornai has elaborated into a system the method of estimating the functional capacity of the heart by auscultation of the sounds audible as an artery is compressed by a Riva-Rocci cuff and the compression then gradually released. The stethoscope applied to the artery below, where it divides, will perceive a maximal systolic sound which becomes rhythmical with each systole as the pressure becomes lower and lower after removal of the compression until the sound finally disappears. There is a regular variation in the intensity and characteristics of the sound heard under these circumstances, varying from the maximum to the minimum of the pressure artificially heightened by the compression. This auscultatory pressure measurement is proving valuable as a means of estimating the functional capacity of the heart, and he tabulates the findings in a number of cases before and during treatment. In one case of Addison's disease conditions in the blood pressure were restored approximately to normal during a systematic course of epinephrin treatment, but in a second, similar case, the abnormal auscultation findings persisted and no benefit was derived from the treatment, the patient soon dying. Tornai urges others to adopt this simple and reliable method of estimating the dependability of the heart and the improvement and strengthening of the heart under appropriate therapeutic and other measures. He adds that it is the most difficult, but at the same time the most satisfactory, task of the physician to estimate in each individual case the actual functional capacity of the heart, conserve its resources and train it to increased functioning. All this is facilitated by this method of auscultation.

175. **Relations Between Disturbances in Innervation and Organic Heart Disease.**—Pawinski comments on the remarkable influence of heart disease on the mind and moods, which feel its influence to a greater extent than is the case even in tuberculosis. Patients with heart disease as a rule do not feel badly or depressed until the fact that they have organic heart disease is revealed to them. The depression that follows is peculiarly aggravated as more serious symptoms follow. With a valvular defect associated with a tendency to neurasthenia or hysteria, or both, there is generally either excitement with unusual cheerfulness or a hypochondriac depression. The first type is observed mostly with a valvular defect of rheumatic origin in the young, of a lively, excitable temperament, fond of sports and excesses. It is possible that the abnormally powerful contractions of the heart, sending exceptionally large waves of blood to the brain and then sucking it all away again may maintain the condition of extreme excitability. This type is also observed with pure mitral stenosis or insufficiency especially in women. The changeability of the objective symptoms is a special feature of this group, the diagnosis wavering between valvular defect, chronic disease of the myocardium and a mere cardiac neurosis. The morose type is most common in men with mitral insufficiency. Recurring dyspnea accompanied by depression, especially in the obese, psychic asthma occurring often at night, especially with a tendency to obesity, during the menopause, and also the climacteric cardiovascular weakness and the dyspnea simulating angina pectoris which is observed at times in men, especially after exercise—all these are due to disturbances in the innervation, but they may blend into or accompany an organic affection. Sometimes the functional disturbances mask the organic trouble or pave the way for their development. Pawinski is convinced that disturbances in the sexual sphere are at the root of most cases of heart neuroses. The knowledge of the relations between the innervation and the circulation is of extreme importance for the general practitioner, he adds, as on this depend not only the prognosis but the whole plan of treatment, and it protects against too exclusive reliance on heart stimulants, while it points the way to effectual psychotherapy.

Books Received

All books received are acknowledged in this column and such acknowledgment must be regarded as a sufficient return for the courtesy of the sender. A selection will be made for review in the interests of our readers and as space permits.

A STUDY OF THE ANATOMY OF WATSONIUS (N. G.) WATSONI OF MAN AND OF NINETEEN ALLIED S[illegible] TREMATODE WORMS OF T[illegible] W. Stiles and Joseph [illegible] alth and [illegible] boratory, [illegible] Pp. [illegible] Wash-[illegible] of Documents] Government Printing Office, 1910.

PULMONARY TUBERCULOSIS AND ITS COMPLICATIONS. With Special Reference to Diagnosis and Treatment for General Practitioners and Students. By Sherman G. Bonney, M.D., Professor of Medicine, Denver and Gross College of Medicine, Medical Department of the University of Denver. Second Edition. Cloth. Price, $7 net. Pp. 955, with 243 illustrations. Philadelphia: W. B. Saunders Co., 1910.

A CONTRIBUTION TO THE COMPARATIVE ANATOMY OF THE PROSTATE GLAND. Being a Thesis for the Doctorate of Philosophy in Biology at the Illinois Wesleyan University, Bloomington, Ill., June 17, 1909. By C. W. G. Rohrer, M.D., Associate Professor of Pathology and Assistant in *Genito-Urinary Diseases*, College of Physicians and Surgeons, Baltimore. Cloth. Pp. 124.

PHYSIOLOGY AND PATHOLOGY OF THE SEMICIRCULAR CANALS. Being an Excerpt of the Clinical Studies of Dr. Robert Bárány with Notes and Addenda Gathered from the Vienna Clinics. By Adolph E. Ibershoff, M.D. And a Foreword by Royal S. Copeland, M.D. Cloth. Price, $1 net. Pp. 64, with illustrations. New York: Paul B. Hoeber, 69 E. 59th St., 1910.

DISEASES OF THE EYE. A Hand-book of Ophthalmic Practice for Students and Practitioners. By G. E. deSchweinitz, M.D., Professor of Ophthalmol[illegible] of Pennsyl[illegible] Surgeon to the [illegible] Sixth E[illegible] $5 net. Pp. [illegible] rations. [illegible] Saunders Co., 1910.

A SYSTEM OF SYPHILIS. In Six Volumes. Edited by D'Arcy Power, M.B., and J. Keogh Murphy, M.C. With an Introduction by Sir Jonathan Hutchinson, F.R.S. Volume IV, Syphilis of the Nervous System. By F. W. Mott, M.D. Cloth. Price, $13.50. Pp. 502, with 57 illustrations. New York: Oxford University Press, 1910.

SURGICAL AFTER-TREATMENT. A Manual of the Conduct of Surgical Convalescence. By L. R. G. Crandon, M.D., Assistant in Surgery at Harvard Medical School. Cloth. Price, $6 net. Pp. 803, with 265 illustrations. Philadelphia: W. B. Saunders Co., 1910.

TWENTY-FOURTH ANNUAL REPORT OF THE OHIO DAIRY AND FOOD COMMISSIONER TO THE GOVERNOR OF THE STATE OF OHIO. For the [illegible] Nov. 15, 1909. Renick W. Dunlap, Commissioner [illegible] Paper. Pp. 93.

LIFE AND HEALTH. By James F. Rogers, M.D., Assistant Instructor Physicial Diagnosis, Yale University. Cloth. Pp. 202. Price, $1 net. Philadelphia: J. B. Lippincott Co., 1910.

THE FAMILY HEALTH. By Myer Solis-Cohen, M.D., Fellow of the College of Physicians of Philadelphia. Cloth. Price, $1. Pp. 267. Philadelphia: The Penn Publishing Co., 1910.

PROCEEDINGS OF THE NEW HAMPSHIRE PHARMACEUTICAL ASSOCIATION AT THE THIRTY-SIXTH ANNUAL MEETING. Held at the Weirs, N. H., June 29 and 30, 1909. Paper. Pp. 125, with illustrations.

FIFTY-SIXTH ANNUAL REPORT OF THE NEW YORK INFIRMARY FOR WOMEN AND CHILDREN. Dispensary, 321 East 15th St., New York, 1909. Paper. Pp. 51.

THE CARE OF THE CHILD. By Mrs. Burton Chance. Cloth. Price, $1. Pp. 242, with illustrations. Philadelphia: The Penn Publishing Co., 1909.

METHODS FOR EXTENDING POPULAR EDUCATION IN PUBLIC HEALTH AND PREVENTIVE MEDICINE*

SENECA EGBERT, A.M., M.D.
PHILADELPHIA

If a text were necessary for my address to you to-day, I should at once select the declaration of the revered Pasteur that "it is within the power of man to rid himself of every parasitic disease." Correlated with this is the more recent and almost equally impressive statement of Prof. Irving Fisher that "fifteen years at least could be at once added to the average human lifetime by applying the science of preventing disease," and that "more than half of this additional life would come from the prevention of tuberculosis, typhoid, and five other diseases, the prevention of which could be accomplished by purer air, water and milk."[1]

Note that this latter authority says that these results could be achieved "at once" and, by inference, with the knowledge that we already possess concerning the causation and elimination of transmissible maladies and the possibilities of preventive medicine. We need not wait indefinitely for further necessary contributions at the hands of those searching for the secrets of unsolved problems of disease; we have abundant equipment for action and results even now.

In raising the question as to why we are not already enjoying a consummation so devoutly to be wished for, I would not have you feel that I desire to minimize or to mar in any way the glory of the wonderful and all-important achievements in the conservation of human life, health and happiness that have already been secured by zealous workers, almost all of whom, I am proud to say, have been members of our beloved profession. Their fame is secure, but their work has only blazed the way and opened up vistas of the far greater possibilities of the future.

Nevertheless, the query is insistent why, where so much is at stake, the potentiality of the future is not already the accomplishment of the present. Considering what physicians actually do and have always been striving to do along these lines, it cannot be fairly said that the incompleteness of the present status is due to lack of either faith or effort on their part. Whether we like it or not, we must realize that the time has come when it is absolutely necessary that others—yes, many others of many varied pursuits and callings—should take up a share of this portion of the "white man's burden" in which the physician has been the pioneer. A striking analogy in the field of human uplift which exists at the present moment will serve to validate this latter assertion.

From time immemorial the clergy of practically all religious creeds have been the leaders in and have done the chief work in all phases of religious activity. The laity have been content to give moral and financial support, more or less hearty according to conditions and circumstances. But suddenly within the last few years there has been developed a tremendous laymen's missionary movement in which are enlisted men of all creeds and denominations, which has already shown great power and influence and which promises to accomplish more in a few decades than has been achieved in many centuries of the past. I could speak of other manifest signs of social awakening, of the realization on the part of the good citizen that he is his brother's keeper, and that active altruism must supplant selfish inactivity and indifference. Therefore, the time is ripe to call the laity to our aid, and already the first steps have been taken toward this end.

Thus, we find not only that do current newspapers and magazines contain with increasing frequency popular articles on subjects pertaining to preventive medicine, but that the American Medical Association has organized a Board of Public Instruction on Medical Subjects—whose work will be largely along the lines that I am indicating—and especially that at our meeting last year in Atlantic City this Section became sponsor for and the Association authorized the Public Health Education Committee, of whose purposes and work I shall have more to say later.

It is entirely unnecessary and it would be a waste of your time and an abuse of your patience even to mention the many subdivisions and phases of preventive medicine which any plan of general popular education for this purpose involves. My desire is rather to discuss some of the means whereby positive results may be most readily secured under present conditions and by which the most profitable expenditure of effort and energy may be made. Nor am I unmindful that some, if not all, of the suggestions may seem trite and commonplace to you who have been for years engaged in the pioneer work of this great propaganda. In my own teaching I constantly find the tendency to overlook or to minimize important features because, through frequent repetition, I have become imbued with the feeling that they must be known and recognized by every one. Nevertheless, we have evidence on every hand that many of the simplest sanitary truths and principles are entirely unknown or unheeded by many of even the intelligent members of our communities. And as some of the most important and most insistent features of our work has to do with those persons who cannot be thus classified, but whose ignorance prevents even the appreciation of the importance of hygiene and prophylaxis, I trust that any review of familiar methods may not seem inappropriate and out of place.

---

* The Oration on State Medicine in the Section on Preventive Medicine and Public Health of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

[1] Abstract of the Report on National Vitality of the Committee of One Hundred on National Health.

Moreover, I shall scarcely attempt to present the several methods in a logical sequence or with any idea of their respective correlation. In fact, I doubt whether one could place them in scientific and orderly array at this time, especially when different localities and conditions demand varying means and application of means. But, as our hope is in the future, and as the children of this generation are to be the citizens of the next generation, I may as well begin with them and with the chief medium of their education, the schools. Schools imply teachers, and so the question arises: Whence come the teachers and what preparation have they had for giving instruction, both subjective and objective, both didactic and practical, on the fundamentals of health and life? Surely no one at this day will cavil at the proposition that physical development is as important as mental, and that every child should be informed as to the functions and needs of the body, as well as of the mind. But we have scarcely appreciated the equally important fact that the future citizen should be taught his duty in conserving the welfare of others and the altruistic aims of modern hygiene and sanitation. Can his teachers give him this training? I think that any extended investigation will convince you that the number of those capable of doing this in a thoroughly satisfactory manner is very small in comparison with the total number. No criticism of the average teacher is altogether fair under present conditions, however, as the blame for his or her inefficiency lies higher up and chiefly with us, ourselves. Really, we are more concerned with the future, provided we date from now.

According to the United States Commissioner of Education, there were in the public and private normal schools of the country for the year ending June, 1909, 82,288 students enrolled in the regular training courses for teachers, and 14,155 graduates therefrom. Added to these, there were in public and private universities, colleges and high schools enough others pursuing teachers' training courses to bring the total up to 103,824; and if the latter institutions "had furnished from their normal students the same proportion of graduates" as did the normal schools, the additional "number would have been 3,704, thus increasing the number of trained teachers to be added to the teaching force of the country in 1909 to approximately 17,859." Provided that each one of these teachers shall have been equipped and qualified to teach what every boy and girl has a right to and should know about personal hygiene, public health and preventive medicine, there is here a mighty power for good whose benefits to the next generation and to the country's welfare no man can calculate. And yet this is but one year's output.

Few here would argue, I take it that any pupil of high-school grade should not be thoroughly instructed in the fundamentals of sanitation and public health, or that our higher institutions of learning should not help to make better citizens along these lines. What a potentiality for good, then, was there enfolded in the 1,034,827 students of high-school grade that the Commissioner of Education tells us were enrolled for the year ending last June, or in the 331,418 students in higher education, even though the proportion of the former was only 11.72, and of the latter, 3.75 to each one thousand inhabitants!

In addition, more than sixteen million other children were enrolled in the public schools of the country in 1909, and it is also estimated that the total number of children from 5 to 18 years of age was 24,613,783, or almost half a million more than the estimated number of males 21 years of age and over. Is it not worth while to attempt to awaken the interest of our superintendents of public instruction and other educational authorities?

Another way of reaching many of these children and some of the adults is through the public playgrounds and recreation centers which are being established in many of our cities. The number of these is already greater than most persons realize. Thus, in 1909, there were 1,535 of them in 267 of the 336 municipalities in which supervised playgrounds are maintained, and in 259 of these cities there were 3,756 persons employed as supervisors and play-leaders. The latter large and increasing body of intelligent men and women, many of whom have had expert training in physical culture, can exert a tremendous influence, not only indirectly by subjectively developing in their charges an active appreciation and desire for health and sound bodies, but directly by inculcating whenever opportunity offers many of the fundamental principles of personal hygiene and public health. That this may be done most happily in an environment of baths, gymnasium apparatus, open-air sports and games for children of all ages must be obvious to all.

Leaving the children for a time, and considering the public at large, we find it no small problem to determine how we may reach and benefit the largest number most efficiently. Those who have undertaken the work have found that no one plan or method will suffice, and that the best intentions and service is oftentimes illy repaid or appreciated. In planning work of this kind, however, it may be said that the methods adopted should be devised so as to attract and hold the attention of the individuals concerned and to convince them that they are personally and especially interested. We cannot afford to ignore the fundamental principles of psychology and pedagogy in this domain.

Heretofore the brunt of what work has been done has fallen on our national, state and municipal health officers and their assistants, and the country will ever owe an irredeemable debt to these men who have done and are doing such valiant service. They realize, however, that the task has grown too large for them, backed, though they are with official power and funds, and they welcome the aid of every progressive physician and earnest citizen who will help to further the physical welfare of the people committed to their care.

Among the efficient means which these health officers have heretofore employed to extend sanitary knowledge are, on the one hand, the weekly or monthly bulletins and the annual reports on the state of health of the communities under their respective jurisdictions, and on the other, the special tracts or pamphlets carrying precise information relating to the precautions to be observed when certain specific diseases occur in either sporadic or epidemic form. The latter have the great advantage that they reach the individual when he is in a highly receptive mood and most likely to heed and to be impressed by the information they contain. As for the bulletins and reports, there is the twofold danger that their distribution may be too much limited, whereby they may fail to reach those whom they might benefit the most, and also that they may fail to interest the average individual by being made simply a compilation of dry vital statistics. There are, however, many of these publications to which this latter criticism does not apply, a notable example being Chicago's weekly bulletin which bears the title "Chicago School of Sanitary Instruction," and which has at its head the statement that it is "sent free to those of our citizens who should be benefited by it." The annual health reports of our states and larger cities also contain much valuable and interesting information, and are worthy of a wider distribution and more extensive study than, I fear, most of them receive.

A number of progressive health officials are now using the newspapers of their territory more extensively than ever before as a means of reaching the public and keeping it in touch with the progress of their work, their needs and their purposes and aims. The Commissioner of Health of my own state, Dr. Dixon, systematically takes his constituency into his confidence by utilizing the facilities of the newspapers of the state to the extent of 600 or more, and the corresponding official of Philadelphia, Dr. Neff, has likewise greatly strengthened his administration in the public estimation by a free and frequent use of the city papers.

Other agents under the direction of directors, commissioners of boards of health are the medical and other inspectors, including school and visiting nurses, all of whom are enabled to give direct, positive and timely instruction and advice to those who most need it and who are often least likely to get it from other sources. School medical inspectors also have demonstrated their value and the enormous advantage they have in detecting abnormalities and defects in their incipiency. Dr. Osler is reported to have calculated that there was in New York City "on account of the lack of medical supervision of educational work a yearly financial loss of $1,666,666," and also to have said in effect that "he considered it of greater importance to the nation that the question of sound teeth be intelligently considered than that the consumption of alcohol be restricted, important as the latter problem is."[2]

Reference to the newspapers calls attention to the fact that in the public press we have one of the most powerful and practicable factors for disseminating information and developing education along our special lines, and that as yet we have barely tested its possibilities. It is only when we realize that we have in this country almost 2,500 daily and over 16,000 weekly newspapers, not to speak of the great number of popular magazines and periodical publications of other kinds, that we can appreciate the opportunity they give us to reach the mass of the population. Moreover, their editors and publishers, almost without exception, are ready and even eager to give us abundant space for anything authoritative that has to do with the improvement of public health. They have realized even more quickly than we have the popular demand for such information. In evidence of this, note the recent increase in the number of magazine articles on health topics.

It certainly should not be difficult to plan measures by which we could make use of this great medium to the fullest extent. Suppose, for instance, a health column supplied by some competent authority were printed in every weekly newspaper in a given state throughout the year—something by no means difficult to secure. Comparatively few families subscribe for and few individuals read more than one of these weekly papers. Hence the same "copy" could be used for many, either simultaneously or by judicious distribution, and the same editorial effort applied to an extended territory. If, too, the state department of health should undertake such work, as is, in fact, being done in my own state, great economy of labor and expense would be secured, the matter for publication would go out with the stamp of authority, and the health department would be brought into that close touch with the people that is so essential for its success.

A caution is to be observed, however, whether state officials or others take up this line of work. Such published matter should be authoritative, educational and not above the capacity of understanding of the average reader. If the series could in part develop systematic instruction along certain lines, so much the better, but care should always be had that misleading or exaggerated statements should not be made, and that statistical or other information should be well grounded in fact.

Magazine articles, such as those by Dr. Woods Hutchinson in recent numbers of the *Saturday Evening Post*, and others with which you are doubtless familiar, are also of great value in fixing and molding opinion, and writers with special talent in this line should be encouraged to contribute their aid to the work. Likewise, publishers of religious, trade, agricultural and other specialized periodicals should also be urged to make the relationships of public health to their respective fields of work frequent and special features of their publications. As I have indicated, the opportunities for disseminating information in this way are almost innumerable.

Life-insurance companies and fraternal organizations that maintain insurance departments are in an especially favorable position to greatly benefit both their own and public interests, and some of them are already seizing the opportunity by official communications to their medical examiners and policy holders. In a circular letter to its medical examiners, dated April 15, 1910, the chief medical director of the Provident Savings Life Assurance Society says:

> The Policy Holders' Health Bureau, established by this society in August, 1909, has passed beyond the preliminary experimental stage. Tangible and practical results are already in evidence, which warrant the prediction of a permanent and growing field of usefulness for the activities grouped under the organization of such a bureau. . . . We have referred to our bureau work as "semi-public," for the reason that as the number of policy-holders benefited by our system increases, the general public will also become informed as to the value of periodical medical examinations, and there will be a growing tendency to employ physicians as inspectors and regulators of human machinery, rather than as necromancers who are expected to work miracles in the cure of established and progressive disease.

Dr. Dwight, medical director of the New England Medical Life-Insurance Company, says:

> For more than sixty years the life-insurance companies of this country have been storing up ammunition and developing an organization which, if properly used, would be almost sufficient in itself to turn the tide of battle for public health in favor of the forces of scientific effort.

Dr. Hiram J. Messenger, actuary of the Travellers' Insurance Company, prepared a table for Professor Fisher's Report on National Vitality, to show that the life-insurance companies could probably make money now by taking a hand in the public health movement, and says:

> This table shows that if the companies were to expend $200,000 a year for this purpose and as a result should decrease their losses by the almost insignificant amount of twelve one-hundredths of 1 per cent., they would save enough to cover the expense. If such a plan as this were placed on a purely scientific basis and carried out by good business methods and all the companies pulled together for the common good, I should expect a decrease in death claims of more than

---

[2] Fisher: Report on National Vitality, p. 73.

1 per cent. And a decrease in death claims of 1 per cent. would mean that the companies would save more than eight times as much as they expended or would make a net saving of more than seven times the expense—which would be about a million and a half dollars a year.

I need not dwell on the importance of public lectures on health topics, but it must be noted that these will not realize their full value for good unless attention be given not only to the selection of speakers and their choice of subjects, but also to proper advertising and the securing of large and interested audiences. In many instances, their values would be enhanced if they were given in connection with public exhibits, such as those on tuberculosis recently held in many of our cities; and in any community there would doubtless be a decided gain if most or all of such lectures in a season were systematized and arranged in a logical course under the superintendence of some organized body, such as a county medical society, women's club, college settlement or the like. It is also advisable that such organizations in the large cities should provide lectures in their respective tongues for the masses of foreign population that we find in certain districts. It may even be advantageous to increase the attraction by illustrating the talks with lantern-slides, or by providing some additional musical entertainment. But it is on these addresses and the visits of medical inspectors, district nurses and other sanitary missionaries that we must chiefly rely for the principal education of these alien masses of our population.

In fact, I would recommend that in each of our towns and cities of moderate size, and in localized districts of the larger cities, there should be organized public welfare clubs, whose chief business should be the carrying on of this propaganda of public health work and sanitary instruction. Such clubs might be independently developed, or they might be made up of representatives from associations and organizations already in the locality, such as the beneficial and fraternal societies, women's or mothers' club, library association, hristian Endeavor and church clubs, etc. They should naturally include the physicians and clergy of the community, and every public-spirited man and woman who has an active interest in neighborhood improvement and the welfare of humanity at large.

Such clubs could thus not only arrange for a systematic course of public lectures and exhibits, but could institute and develop public health measures and improvements of all kinds. You will at once realize the many lines of activity which they might follow. They could call on the central health department of the state for statistics, charts and other material for exhibits on tuberculosis, typhoid fever, etc., and, in passing, I would remark that it would be well for the state health departments to have such exhibits prepared for the special use of just such clubs and organizations, which could use them in turn and on proper request and notification. The winter course of lectures would include discussions of local sanitary conditions, the dangers of patent medicines, the prophylaxis of social disease, the theory and use of antitoxins and vaccines, as well as the ordinary questions of hygiene, and would soon be appreciated by the public as of great educational value.

Organizations such as these could also make use of a means of arresting and fixing public attention that has as yet been too rarely employed—the public poster. These posters, which have already been used in some of the large cities, as in Philadelphia and Chicago, are probably more practicable in smaller communities, because the smaller number needed greatly reduces the expense. Notwithstanding the multiplicity of newspapers and magazines and the opportunities they offer for exploiting our work, we must realize that not only do many of their users peruse them but carelessly and hurriedly, but also that many of the general public do not read them at all. Hence we should provide some other means by which "he who runs may read" and whereby he may be induced to take heed of that which is for his own or his neighbor's welfare. This the poster does, and it may be used in all sorts of places, such as billboards, shop-windows, street-cars, etc., where it will catch the eye and fix attention.

Care should be taken not to attempt too much on a single poster, since an excess of reading-matter in small type may lead to a failure to attract due notice. A few pithy, epigrammatic sentences, or often a single one, with at times a touch of local or timely wit, or, perhaps, a sketch or cartoon, will do more to fix the purport of the poster in the minds of those who take it in at a glance in passing than will a lengthy exposition that requires a halt of five minutes or so for its reading. We can afford to take a lesson here from successful advertising agents whose business it is to know human psychology to the end that they may drive impressions home within the space of the fleeting moment.

I feel confident that the judicious use of such posters in a community of moderate size would do much to secure public attention and excite comment, and that the public welfare clubs, health officers or others may well employ them to do what the newspaper and magazine articles cannot do. The poster will also be especially useful when printed in other tongues than our own and properly distributed in the foreign districts of our larger cities.

A failure to mention the potential assistance which we may have from the clergy and our churches would be to lose sight of a most important and powerful component of our body politic. The signs of the times show most positively that henceforth the minister to the soul and the physician to the mind and body must be more closely linked in their labors than ever before, that they must work together and not pull apart or against one another, and especially that this great field of preventive medicine is the domain of both. Ministers of all denominations should be encouraged properly to encourage and to instruct their congregation in the acquisition of the fundamental principles of bodily hygiene and altruistic sanitation and in the appreciation of these as important and necessary to the securing of spiritual health. Churches and parish-houses which now are idle on too many week-days should be opened and used for public lectures and meetings. What places could be more appropriate for joint talks from pastors and physicians on questions that pertain to the proper instruction of youth, the abuse of alcohol, social purity, etc.? Where better could the two professions join to combat false gods and dangerous doctrines? The physician can assist the preacher by giving him sound information and trustworthy data for his sermons, and by encouraging him in dealing with such topics, and the preacher can support and help the physician in his campaign against all that makes for disease and pain and suffering in their common neighborhood. That the congregation can do much in doing their share of the work, if they are only shown the way, is so obvious that I need but mention it.

Within the past few years the Department of Health of Pennsylvania has established 114 tuberculosis dispensaries, which are doing much good in an educational as well as philanthropic way. The professional nurse, who is attached to each of these dispensaries is especially valuable in this direction and "her ministrations amount to a liberal education in the treatment of tuberculosis." She not only makes a first-hand investigation of each patient's case, securing data as to his family history, occupation, financial resources, etc.; but she visits him at his home and there instructs him and the other inmates as to his proper care and handling, how the others are to escape infection, and especially devotes particular attention to diet, telling the housewife what to cook and how to cook it. Thus far over 130,000 of such visits have already been made, each one affording an opportunity for instruction in sanitary details with a direct and immediate application thereof. The value of such educational work needs no argument for its appreciation.

I might continue to consider with you other ways and means for carrying on this missionary work of ours, but your patience may be approaching the limits of tolerance. Therefore, as the last but by no means the least of these beneficent and efficient agencies to which your attention is directed, I trust you will give full support and encouragement to the work and efforts of the Public Health Education Committee that had its inception in this Section a year ago.

No one at this time can afford to deny that one of the most powerful factors in general public uplift and especially in the extension of the very work in which we are interested, is the collective influence of the good and intelligent women of this country, as manifested not only in their special clubs, mothers' meetings, etc., but also in their individual homes and neighborhoods. It is this influence which the Public Health Education Committee desires to weld and unify into a mighty agent for this special work, and both this attempt and the primary endeavor to enlist in the campaign the women members of the American Medical Association is, I believe, worthy of our hearty commendation and support. Here certainly is a wide field for the energies of the woman physician and none of us need feel jealous or envious of her entry on it. She can do more in certain directions than can the man; she has more leisure and adaptability for certain phases of it, and she can bring in, as the man cannot do, the joint influence and power of other women's organizations that will all work for better and healthier homes, communities and the common country. Let us congratulate the committee, therefore, on what it has already accomplished and help it to do still more in the future.

I shall not take time to do more than to mention the work of our Board of Public Instruction in Medical Subjects, for I assume that you are all so familiar with it that nothing that I could say would add to your sense of its importance, especially in this field of ours.

With this review of the means at our command, and from which many details have necessarily been omitted, I trust that I have made you feel that we are well armed for the educational campaign which must be conducted before we can hope to secure the results in the conservation of life, health and human vitality that we know it is in our power to have. Dr. Rosenau has recently said:

> The public health militia that I have in mind calls for the enrollment of all good citizens. Preventive medicine is the watchword of the hour, and enlistment in the cause can come only through education. There are two important factors in efficient public health work. One is the gaining of new knowledge through scientific research; the other is the diffusion of this knowledge through education. The two go *hand in hand*. Not only the medical profession, but the people must be the reserve militia in any effective warfare against disease.

Professor Fisher likewise says in the conclusion of the summary of his report from which I have already quoted:

> Money estimates of waste of life are necessarily imperfect and sometimes misleading. The real wastes can only be expressed in terms of human misery. Poverty and disease are twin evils and each plays into the hands of the other. From each springs vice and crime. Again, whatever diminishes poverty tends to improve health, and *vice versa*. . . .
>
> The conservation of our natural resources—land, raw materials, forests, and water—will provide the food, clothing, shelter and other means of maintaining healthy life, while the conservation of health likewise tends in many ways to conserve and increase wealth. The more vigorous and long-lived the race, the better utilization it will make of its natural resources. This will be true for two reasons in particular: First, the greater inventiveness or resourcefulness of vigorous minds in vigorous bodies. Civilization consists chiefly in invention and the most progressive nations are those whose rate of invention is most rapid. Second, the greater foresight and solicitude for the future. As it is usually the normal healthy man who provides life-insurance for his family, so it will be the normal healthy nation which will take due care of its resources for the benefit of generations yet unborn. . . .
>
> Federal, state, and municipal boards of health should be better appreciated and supported. Their powers of investigation, administration and disseminating information should be enlarged. School hygiene should be practiced, and personal hygiene more emphasized. The multiplication of degenerates should be made impossible.

If one state, through the administration of one man and his staff and supported by the hearty co-operation of its municipal and county health officers, can within four years not only organize and establish a department of health almost *de novo*, but also show a positive saving to the commonwealth of $23,000,000 of human life value with an expenditure of $3,000,000; if it can, as Pennsylvania has done, within that time cut the typhoid mortality to less than half that it was before, bring down the tuberculosis death-rate from 134 to 120, and show a net saving of almost 14,000 lives, *is there not* every encouragement to continue with renewed energy whatever efforts we have been making in the past? Even though we are tempted at times to feel that much of the seed falls among thorns or on stony ground, we have no reason or right to conclude that the sowing is not well worth while; that the labor will not bring a bountiful harvest. Fortunate is he whose field of endeavor shows the promise of a more abundant reaping or fuller granaries in the end.

THE INSTITUTIONAL TREATMENT OF NERVOUS AND MENTAL DISEASES*

THEODORE DILLER, M.D.
Clinical Professor of Neurology, University of Pittsburg
PITTSBURG, PA.

It is my pleasant duty in opening the proceedings of this Section to thank you for the honor you have bestowed on me in making me the Chairman of the Section for the year. I may further say that the honor is a real and unexpected one; for the first intimation which I had that I was to be chairman for the year was the report of the nominating committee to the Section at the meeting of the Association last year at Atlantic City. And this leads me to believe that, whatever may be said of the past, or of any other Section of this Association, in the Section on Nervous and Mental Diseases, medical politics plays no part whatever.

---

* Chairman's address before the Section on Nervous and Mental Diseases of the American Medical Association, at the Sixty-first Annual Session, St. Louis, June 7-10, 1910.

I believe that it should be the aim of this Section to discuss all the varied phases of nervous and mental diseases, and that its officers should endeavor to assemble together the best available men in the country on its program. And I further believe that it should be the especial aim of this Section to present the subjects of neurology and psychiatry in such clear, simple and attractive manner that its proceedings may serve to interest and instruct not only neurologists and alienists, but also general practitioners and internists and a certain number of those whose field of activity lies in work in other specialties. It may be truthfully said that the problems which engage the interest of the members of this Section also possess in themselves more or less interest for all members of the profession. Neurology and psychiatry in their several aspects and in their manifold interests call on those who pursue them as specialties to take more or less account of every other department in the broad domain of medicine and, indeed, much outside it, for example, law, social science and penology.

It is with this understanding of the subject that I have endeavored to cooperate with our secretary (and to work with him has been a genuine pleasure) in making out the program for this meeting.

The criticism is often made of programs of associations of neurologists and alienists that they present little or nothing on the subject of treatment; and for one, I have the feeling that this reproach is not wholly undeserved. Hence it has been our aim in making up the program for the Section this year to secure an unusual number of good and practical papers dealing with the treatment of nervous and mental diseases; and I believe that if you will look over the program in your hands you will agree with me that we have attained a very fair measure of success.

I wish to address the Section briefly on a subject which I believe to be one of vast and far-reaching importance, even though I shall be able to speak only in general terms and must treat it most inadequately and leave much that I should say unsaid. I refer to the institutional treatment of nervous and mental diseases.

This subject becomes one of vast importance when we consider the large number of patients for the adequate or proper care of whom institutional treatment is required. In nearly all cases of insanity institutional treatment is demanded and received; in nearly all the severer cases of inebriety institutional treatment is demanded, but in few is it received; and very many of the cases of organic and functional nervous diseases demand and some receive institutional care.

As years go by and hospitals for the insane improve their equipment, and as the public becomes better educated as to the value of institutional treatment for the insane and less and less suspicious of these institutions, the percentage of insane and feeble-minded outside of hospitals grows less and less, and these institutions everywhere throughout the broad land are becoming more crowded. Nor does the provision for additional accommodations in any state in the Union keep pace with the growing demands for such accommodations. Despite many drawbacks and obstacles, and despite the great work of improvement which yet remains to be accomplished, these institutions have made fair progress in their methods and equipment for the care and treatment of the insane and feeble-minded.

In this connection I desire to direct attention to the subject of the treatment of insane in institutions other than regular hospitals or asylums for the insane. So far as I know, there are only two general hospitals in the United States—St. Francis Hospital, Pittsburg, and Albany Hospital, Albany, N. Y.—which are equipped to receive insane patients. There are several large hospitals for the insane which are departments of general hospitals, but which possess separate buildings and separate managements and must be regarded as practically separate institutions.

I wish to say a word here regarding St. Francis Hospital in Pittsburg and its work to illustrate some of the points I wish to make. This is a large general hospital and has connected with it a psychopathic ward. In this ward or department there are about 100 patients, including a great many acute cases; and it has been the aim to have only acute cases in this department. A resident physician and intern devote all their time to this department, which is under the medical direction of three visiting physicians. The members of the medical and surgical staff are frequently conferred with regarding these patients. While the psychopathic department of St. Francis Hospital is not entirely ideal and much remains to be done to make it so, yet it stands for a most valuable principle, namely, the treatment of insane in a general hospital. This means much, very much. Our experience at St. Francis is that patients suffering from acute psychoses are admitted early, and that their friends do not feel that the same stigmata is placed on them going to and coming from this hospital as in the case of the regular hospital for insane. It is well known that certain psychoses can be and have been treated in general hospitals, but the difficulty is that if such patients become noisy or troublesome the management generally demands their removal. I am strong in the conviction that in every large city there should be at least one general hospital ready to receive cases of insanity and equipped to treat these patients. A large general hospital can easily have a properly equipped wing or even detached section to hold 25 or 50 patients, and thus it can accomplish a great purpose and fill a great need in any large community. The noise and disturbance of such patients can be kept from the general hospital if the wing or separate building is properly planned and built.

Psychiatry should be regarded as a department of internal medicine, and I trust that the time will come when the psychoses will be discussed in general textbooks in the practice of medicine. And the day is coming also, I trust, when patients with acute psychoses will receive treatment in general hospitals and not have to go to hospitals for the insane unless the disease is unduly prolonged or appears to be incurable. When the treatment of insanity is undertaken by general hospitals, as I have indicated, I believe that an entire change will come over the profession and the public regarding their attitude toward the insane. The profession will realize in a practical way that what is called insanity is an expression of sickness; and the laity will learn the same lesson. Another result would be that the skill of the various specialties would be brought to the insane; and these patients would be a constant source of education for all physicians connected with hospitals maintaining such psychopathic departments. And then psychoses would be described in the textbooks on the practice of medicine and the general profession would learn something about them.

It appears to me that, viewed from almost any aspect, the treatment of insanity in general hospitals is greatly to be desired and promoted. Nor do I believe that separate psychopathic hospitals, isolated and apart from the general hospital, possess the advantage which a psychopathic division of a general hospital possesses; for sooner or later they are sure to be regarded by the general public as "insane asylums."

There is a large and sadly growing class of individuals for whom large provision should be made for institutional treatment and for whom such provision is now sadly lacking if we are to hope to give anything like adequate treatment; I refer to the inebriate, addicted to the excessive and uncontrolled or uncontrollable use of alcoholic drinks or morphin, cocain or other drugs. The present inadequate treatment of inebriety is to-day, in my opinion, a standing reproach to society and to the medical profession. The inebriate who seeks or whose family seeks for him institutional treatment meets at all hands with invitations from quackish institutions whose treatment in the main is simple humbug. And yet I think that it will be generally admitted that for a large number of inebriates there can be no adequate treatment, indeed none worth the name, other than that afforded by a well-equipped institution. And such institutions are few in number; so few, indeed, that many an honest practitioner knows not where to find even one for his inebriate patient.

While there is and will be an increasing number of private institutions for inebriates, these are and must be wholly inadequate to meet the needs of the situation. As the result of much thought and investigation, I have reached the conclusion that the several states must provide separate institutions for inebriates, and such institutions should be governed by clear, adequate and comprehensive laws.

Massachusetts and Iowa are, so far as I know, the only states which at present maintain state hospitals for inebriates; and both have adequate laws governing them. We are fortunate in having with us at this meeting Dr. Neff, the superintendent of the Massachusetts State Hospital for Inebriates, who is to tell us of the workings of that institution. Minnesota is about to provide a state institution for inebriates, and the subject has been urged before the New York and New Jersey legislatures, but as yet without success.

In Pennsylvania, the state medical society has for several years been trying to persuade the legislature to build a state hospital for inebriates. A bill providing an appropriation for the creation of such an institution was passed by the last assembly; but it was vetoed by the governor because of his belief that the financial situation would not warrant this new expenditure. Pennsylvania already has a law which provides that an inebriate may be committed by a judge, after a hearing, to a "proper hospital or asylum" for a period not to exceed one year. Under this law, a number of inebriates have been committed to various hospitals for the insane throughout the state. Superintendents of these institutions are unanimous in saying that they do not desire these patients, as they do not properly belong there, that they are hard to get on with and upset the discipline of the institution. On the other hand, the inebriate himself strongly resents being committed to an insane asylum; and in consequence he goes there, when compelled to, in a frame of mind little calculated to effect a restoration to health having in it the elements of stability.

Our argument to the Pennsylvania legislature has been brief and to the effect that the adequate treatment of inebriety requires a separate and properly equipped institution and a proper law governing it and the inebriate. It was urged that, since the state has taken the first step in providing a law governing inebriates, it should logically take the second step and provide the institution which the law contemplates. We hope next winter to succeed in our endeavors with the legislature.

Thus it will be seen that already a start has been made in the matter of provision of state institutions for inebriates and I trust that in the near future we shall see the establishment of many such institutions, so that ultimately every state shall possess at least one.
